Change

Change in general may be defined as the variation of properties (whether of things or of regions of space) over time. But this definition is incomplete in a number of respects. The reference to properties and time raises two important questions. The first concerns whether we need to specify further the kinds of properties which are involved in change. If we define change in an object as temporal variation of its properties we are faced with the problem that some properties of an object may alter without there being a consequent change in the object itself. The second question concerns the passage of time: does temporal variation constitute change only in virtue of some feature of time itself, namely the fact (or putative fact) that time passes? Some philosophers have wished to reject the notion of time's passage. Are they thereby committed to a picture of the world as unchanging?

1 Cambridge change

In *The Principles of Mathematics* (1903), Russell defines change as follows:

> Change is the difference, in respect of truth or falsehood, between a proposition concerning an entity and the time T, and a proposition concerning the same entity and the time T', provided that these propositions differ only by the fact that T occurs in the one where T' occurs in the other.
>
> (Russell 1903: §442)

Geach (1969) has dubbed this kind of change 'Cambridge change', a term now familiar in the metaphysical vocabulary. Note that Russell defines change *simpliciter*, not specifically change in an entity, even though the definition is restricted to propositions about entities. But if we took it as a criterion for change in an entity, then we would have to allow that, for example, a cup of tea changes, not only when it cools down but when someone forms the intention to drink it. This second change passes Russell's test, since 'At T someone intends to drink the tea' is false, and 'At T' someone intends to drink the tea' is true. Yet, intuitively, someone's merely forming the intention to drink the tea is not a genuine change in the tea itself. We need something stronger than Russell's 'Cambridge criterion', as we might call it, if we wish to analyse genuine change in objects. Two possibilities will be briefly sketched here.

An object 'Cambridge-changes' if merely its relations to other objects change, as when for example it becomes smaller than another object simply because the latter has grown in size. If we can distinguish an object's *intrinsic* properties from its *extrinsic* properties, then we can define genuine change in an object as the variation over time of its intrinsic properties. We might attempt to characterize 'intrinsicness' as follows: *F* is an intrinsic property of *x* if and only if *x*'s being *F* does not logically depend upon the existence or properties of any other object. On this account, being an aunt, being ten yards from the top of Mount Etna and being read about do not count as intrinsic properties, whereas being ten yards in diameter and made of lead do count as intrinsic. However, this characterization is not without its difficulties. Change of shape is, surely, a genuine change in an object, but the shape of a thing does not count as intrinsic on the above criterion since having shape is, arguably, not logically independent of the existence of the containing space.

An alternative means of strengthening the Cambridge criterion employs the notion of causality. A genuine change in an object must, on this account, involve causal consequences contiguous to the object. This is not true of, for example, becoming an aunt or becoming famous - the effects of such 'changes' need not be near the object in question. Instead of defining real change in terms of intrinsic properties, we could define the intrinsic properties of an object as those whose alteration *must* involve contiguous effects. On this account, shape turns out, as we would expect, to be an intrinsic property of an object. But we cannot simply define real change in *x* as alteration which *must* have effects contiguous to *x*. The 'must' in italics is surely weaker than a logical must: there is no contradiction in supposing a change in mass, for example, to have no contiguous effects. But then if 'must' means instead 'must according to physical laws' then some mere Cambridge changes would pass the causal criterion. If *x* undergoes the Cambridge change of becoming less massive than some *y* as a result of *y*'s increase in mass, then this must (in the physical sense) have gravitational consequences, however small, in *x*'s vicinity. However, the chain of events leading to these effects in *x*'s vicinity must have started in *y*'s vicinity, so we could modify the account as follows: a real change in an object is such that, if it has effects, these must (in the physical sense) be mediated by effects contiguous to that object.

2 Change and the passage of time

In developing his famous argument for the unreality of time, McTaggart (1927) quotes, and proceeds to criticize, Russell's definition of change (see McTaggart, J. §2). McTaggart's first criticism is, in effect, that real change must involve, not difference in truth-value between *different* propositions, but alteration in truth-value of the *same* proposition. Suppose, to use McTaggart's example, a poker is hot on Monday and cold thereafter. Now it is true at all times that the poker is hot on that particular Monday and cold thereafter, so these facts about the poker do not change. The only real change consists of the fact that the poker's being hot is first a present state and then a past state. In other words, real change implies the passage of time.

Why should we accept this objection of McTaggart's? Let us describe the event of the poker's cooling down, that is its being hot at T and cold at T', as a first-order change. Then McTaggart seems to require a second-order change: the change in the event as it shifts from future to present to past. So it remains to be seen why someone who denies the existence of second-order change, but accepts first-order change, should be thought to be denying change altogether.

McTaggart, however, has another objection. We can construct a spatial analogue of Russell's Cambridge change: there are two spatial points, S and S', such that the proposition 'At S [for example, London] the Greenwich meridian is within the UK' is true, while the proposition 'At S' [for example, Paris] the Greenwich meridian is within the UK' is false. Now this purely spatial variation is clearly not change, but why not? It will not do to say that Russell's definition of change involves times and so excludes purely spatial variation, for this leaves unanswered the deeper question of why time, not space, is the dimension of change. A number of writers who deny that time passes have addressed themselves to this question. One account has it that time is the dimension of causality (since causes must precede their effects) and real change involves causally connected states.

A third argument, not considered by McTaggart, may be advanced for the view that real change in objects must involve the passage of time. It is a commonplace that, for an object to be said to undergo change, it must be the same object which first has one property and then loses that property (see Continuants §1). However, if we deny that time passes, then we must also deny that things can 'move through' time in order to have different properties at different times. Or, if this kind of talk is too metaphorical, we may put the point in the following terms. In order to have a property (or at least an intrinsic property) at a time, an object must exist at that time. Since change takes place over time, an object cannot change unless it exists at more than one time. But now suppose that there is no passage of time and that every proposition about an object is, if true, true for all times. Then, if *x* is F at T and Not-F at T', then it is true for all times both that *x* exists at T and that it exists at T'. Is this not a contradiction? An influential solution to this problem is to say that objects are extended in time in the same way as they are extended in space: that is, they have different (temporal) parts at different times, just as your feet are located in different regions of space. But this introduces another problem, for neither the temporal parts of a thing, nor the collection of temporal parts which constitutes the temporally extended object, can be said to change in the sense we have defined it. A temporal part is confined to an unextended instant and so cannot have different (intrinsic) properties at different times; and the properties that can be attributed to the collection as a whole, such as occupying threescore years and ten, do not vary over time (see Continuants §2).

An adequate account of change, therefore, needs to address these questions: is there such a thing as McTaggart's second-order change in the temporal properties of events? If there is not, must we think of things as having temporal parts? If we must, can we reconcile this with the apparently obvious fact that things change?

Chaos theory

Chaos theory is the name given to the scientific investigation of mathematically simple systems that exhibit complex and unpredictable behaviour. Since the 1970s these systems have been used to model experimental situations ranging from the early stages of fluid turbulence to the fluctuations of brain wave activity. This complex behaviour does not arise as a result of the interaction of numerous sub-systems or from intrinsically probabilistic equations. Instead, chaotic behaviour involves the rapid growth of any inaccuracy. The slightest vagueness in specifying the initial state of such a system makes long-term predictions impossible, yielding behaviour that is effectively random. The existence of such behaviour raises questions about the extent to which predictability and determinism apply in the physical world. Chaos theory addresses the questions of how such behaviour arises and how it changes as the system is modified. Its new analytical techniques invite a reconsideration of scientific methodology.

1 Defining chaos theory

Although there is controversy over the proper scientific definition of chaotic behaviour, chaos theory may be defined as the qualitative study of unstable aperiodic behaviour in deterministic nonlinear dynamical systems.

A dynamical system is a mathematical entity that usually results from the attempt to model a situation in the natural world (see Models). It has two components: a procedure for producing a mathematical description of the instantaneous state of a physical system, and a rule (the evolution equations) for transforming the current state description into a description for some other time. For some dynamical systems, the evolution equations yield a simple formula that allows the direct calculation of future states of the system.

The dynamical systems of interest for chaos theory contain nonlinear terms in the equations. These terms, such as x^2 or $\sin(x)$ or $5xy$, usually render an exact solution impossible. Researchers into chaotic phenomena instead seek a qualitative account of the system's behaviour, investigating the general character of its long-term behaviour, rather than seeking to arrive at numerical predictions of its exact future state (this special sense in which chaos theory is 'qualitative' must not be understood as contrasting with 'mathematical'). For example, a qualitative study of a planetary system would seek to discover what circumstances will lead to elliptical orbits as opposed to hyperbolic ones. This approach is called 'dynamical systems theory' (or sometimes simply 'dynamics') and began with the work of Henri Poincaré. Chaos theory is a specialized application of dynamical systems theory that typically treats such questions as: what characteristics will all solutions of this system ultimately exhibit? and, how does this system change from exhibiting one kind of behaviour to another kind?

Dynamical systems are usually studied in terms of trajectories in state space (sometimes called 'phase space'), a mathematically constructed abstract space where each dimension corresponds to one variable of the system. Every point in state space represents a full description of the system, and the evolution of the system manifests itself as the tracing out of a path, or trajectory, in state space. It is often possible to study the geometric features of these trajectories, even in actual experimental systems, without explicit knowledge of the solutions they represent. This allows one to characterize trajectories according to their topological features, and the investigation of how those features change as the parameters of the dynamical system are altered.

While qualitative questions can be asked about almost any dynamical system, chaos theory focuses on certain forms of behaviour - behaviour which is unstable and aperiodic. The form of instability known as sensitive dependence on initial conditions is a distinguishing characteristic of chaotic behaviour. A dynamical system that exhibits sensitive dependence on initial conditions will produce markedly different trajectories for two initial states that are initially very close together. In fact, given any specification of initial conditions, there is another set of initial conditions arbitrarily close to it that will diverge from it by some finite distance, given enough time. In most chaotic behaviour, sensitive dependence on initial conditions results from the exponential growth of any small initial difference. It is this instability that makes chaotic behaviour unpredictable (see §2).

Aperiodic behaviour occurs when no variable describing a property of the system undergoes a regular repetition of values. Furthermore, chaos is an appropriate label only when such behaviour occurs in a bounded system. An explosion thus does not qualify as chaotic behaviour. And systems studied by chaos theory bear the label

‘deterministic’ because their equations make no explicit reference to chance mechanisms (see §3).

For a dissipative dynamical system, characterized by the gradual loss of energy, trajectories in state space will asymptotically approach a shape known as an ‘attractor’ when transient effects have died away. Until the advent of chaos theory, only three types of attractor were generally recognized: the fixed point (corresponding to eventual equilibrium), the limit cycle (corresponding to periodic behaviour), and the torus (corresponding to behaviour with multiple periods in rationally incommensurable ratios). Chaotic behaviour in dissipative systems requires the introduction of a fourth variety: the so-called ‘strange attractor’.

A crucial geometric feature of strange attractors is their combination of stretching and folding. The action of such a system takes nearby points and ‘stretches’ them apart in a certain direction, thus creating the exponential divergence responsible for unpredictability. But the system also acts to ‘fold together’ points that are at some distance, bringing about convergence of trajectories in a different direction, and hence asymptotic attraction.

The stretching and folding of chaotic systems gives strange attractors the distinguishing characteristic of a nonintegral, or fractal, dimension. These attractors often appear as stacks of two-dimensional sheets packed in a self-similar structure that seems to intrude into three-dimensional space. The dimension of such an object - more than two but less than three - describes its scaling properties, giving a quantitative indication of the stretching and folding at work in the dynamical system. Another quantitative characterization of chaotic systems is given by the Lyapunov exponents, which measure the degree of sensitivity to initial conditions and thus the degree of unpredictability.

It should be noted that strange attractors appear only in dissipative systems. For systems where energy is conserved, there is no convergence onto an attractor. Instead, trajectories are confined to a surface of constant energy in state space. Chaotic behaviour can occur in such systems, but the trajectories will fill the allowed energy surface (which may itself display an extremely complicated structure).

The examination of the transition to chaotic behaviour has yielded important results for understanding the way complex behaviour arises. For example, period-doubling behaviour is found in a wide variety of nonlinear systems, and this type of transition has certain universal features. This universality allows us to make exact predictions about a system’s period-doubling behaviour as soon as we have verified that certain qualitative conditions hold.

Sensitive dependence on initial conditions, strange attractors and other elements of chaos theory have been reported in experimental systems in the physical and biological sciences. Some of these examples of chaotic behaviour have been convincingly documented in laboratory settings, while some of the examples of chaos outside the laboratory are the subject of lively debate.

2 Predictability

Moderately accurate initial conditions will always allow us to predict the chaotic behaviour of a system for some short time into the future, but since the vagueness in our initial conditions grows exponentially with time, we can see that for some chaotic systems, a useful prediction would require initial conditions to be specified with more accuracy than is possible. Inaccuracy can be due to equipment error, ineliminable perturbations from outside influences, round-off error in the representation of real numbers, or even the inherent indeterminacy of the quantity being measured.

Some may contend that so long as the prediction task for a chaotic system requires only some finite degree of accuracy, it is incorrect to say that such accuracy is impossible to achieve.

Since chaos theory, unlike special relativity or quantum mechanics, introduces no new fundamental postulates about the physical world, it provides no new physical theory that rules out the possibility of such predictions. Yet these same systems may nevertheless be unpredictable *in principle* because our inability to make such calculations in the longer term is not due to some constraint we could overcome. The very finitude of human resources implies that it is impossible to obtain the accuracy necessary for predictions.

The limitation posed by chaotic systems presents a challenge to the methodological assumption that a small amount of vagueness in measurements will lead to only a small amount of vagueness in predictions. The standard

technique of perturbation analysis treats a difficult case as a version of a predictable system plus some small 'perturbation' that complicates the situation but keeps it mathematically tractable. Sensitive dependence guarantees that such approximative techniques will be worthless, thus calling into question some of the metaphysical beliefs that underwrite their general applicability. One such belief is the conviction that systems governed by simple rules must behave simply.

3 Determinism

Scientists and philosophers use the term 'determinism' in several senses (see Determinism and indeterminism §1). By one criterion, a system is deterministic if the way it changes in time can be specified by a set of equations that make no reference to chance. That is, there are no probabilities built into the state description due to an averaging over many indistinguishable substates, and the evolution equations do not involve probabilistic branching. Thus, the systems treated by chaos theory are deterministic by definition.

Another criterion consists in the uniqueness of a system's evolution: if two systems are identical in physical properties at one time, they must remain identical at all other times. That is, the complete instantaneous description of a deterministic system 'fixes' the past and future with no alternatives.

A third notion of determinism is that a system is predictable in principle by an all-powerful intelligence or computational scheme, given complete information of instantaneous conditions and the complete set of physical laws. Since measurements and calculations cannot be made with unlimited accuracy, a chaotic system will be unpredictable even though it satisfies other requirements for determinism. In other words, we may not be able to tell *which* unique trajectory a system is following, but that does not mean such trajectories do not exist.

On one interpretation, the randomness and apparent indeterminism of chaotic behaviour are merely artifacts of our epistemic limitations. Another interpretation would treat unique trajectories as inadmissible idealizations, arguing against uniqueness of evolution in chaotic behaviour. This instrumentalist approach argues that there is no point in insisting that the future is fixed, given the present, if that future cannot be predicted.

A third approach would draw on the implications of quantum mechanics to show that unique evolution encounters difficulty due to the workings of chaotic dynamics on intrinsically indeterminate quantities. Such an approach would require an account of how to combine the Newtonian formulations of nonlinear dynamics with the mathematical formalism of quantum mechanics - the difficult task of making sense of 'quantum chaos'.

4 Chaos and scientific understanding

One of the apparent paradoxes of chaos theory is that it represents a scientific study of unpredictable systems that actually has significant predictive power. Chaos theory provides an understanding of how predictable large-scale or long-term patterns appear in behaviour which is nonetheless unpredictable in detail. It may seem odd to assert that chaos theory has 'great predictive power', but such claims refer not to an ability to predict the exact value of some property of a system, but to an ability to foresee and understand changes in the overall behaviour of that system. The crucial point here is the distinction between specific *quantitative* predictions, which are typically impossible for chaotic systems, and *qualitative* predictions, which are at the heart of dynamical systems theory.

The fruitfulness of chaos theory militates against the methodological assumption that it is always appropriate to seek to understand the behaviour of a system by trying to determine the equations governing the interactions of its parts (see Reduction, problems of). For most nonlinear dynamical systems, such a reductionist strategy does not help us understand how the chaotic behaviour sets in, or what kind of attractor characterizes it, or how the system will respond to changes in parameters. Understanding this behaviour requires the use of the new mathematical techniques of nonlinear dynamics. While chaos theory argues against the universal applicability of the method of reductionism, it provides no examples of 'holistic' properties which could serve as counter examples to metaphysical doctrines of reductionism, such as physicalism.

Chaos theory shows us the mechanisms responsible for unpredictable behaviour, but these mechanisms are best characterized as geometrical rather than causal. Systems with very different underlying causal substrata are grouped together in order to study their qualitative behaviour. Chaos theory does not need to reveal the causal process at work, and it would be impossible in principle to trace out the workings of the actual causal mechanism

in a chaotic system. To do this would require calculations using the evolution equations of the system.

According to some accounts, science furnishes understanding by widening the scope of events that happen out of necessity and not contingency - by revealing laws of nature and subsuming phenomena under them (see Explanation §2). While chaos theory establishes powerful generalizations, its practitioners do not portray their work as discovering new laws of nature. For instance, there is no set of necessary and sufficient conditions that would allow us to foresee which type of transition to chaotic behaviour a system will follow. Chaos theory emphasizes finding patterns and connections, while jettisoning the requirement that the patterns must yield necessity in a detailed and deterministic sense. Some may contend that this search for patterns actually constitutes striving to discover new laws governing qualitative features of systems.

Perhaps chaos theory does not provide us with any genuine understanding at all. After all, it does not introduce any fundamental revisions in our laws of nature. Some might argue that it merely introduces stop-gap measures for data analysis in systems with intractable equations. Perhaps it is only a source of new observations or empirical generalizations. But nonlinear dynamics does require a wholesale revision of notions about the applicability of classical models, and provides powerful new analytic techniques. It should not be disparaged on the grounds that fundamental theoretical structures are left unchanged.

5 Applications outside the natural sciences

Chaos theory has attracted attention from outside the natural sciences. In the social sciences, the techniques developed for analysis of nonlinear systems have been applied to economic data, for instance. Such techniques can determine the extent to which random fluctuations in a chosen variable can be modelled with simple deterministic mechanisms.

Sensitive dependence on initial conditions has also served as a metaphor for the precarious swings of human history. Metaphorical interpretations of chaos theory have also appeared in natural theology and literary theory. Other areas where chaos theory may have philosophical implications are: the foundations of statistical mechanics, the problem of freedom of the will, and the role of the cultural context of science.

Charity

Within at least some branches of Christianity, the term 'charity' has been used to mean the love mandated by Jesus. In recent theological writings, however, there has been a tendency to replace it with the Greek word agapē*. There has been some disagreement in the twentieth century concerning the precise nature and functioning of Christian love, a major catalyst for debate having been Anders Nygren's book Agapē and Eros (1930-6). Numerous scholars have complained that charity does not have a high profile nowadays and have noted that, in common parlance, the word usually has the meaning of benevolence or beneficence. Some attempts have been made to place greater emphasis on Christian love and relationships within Christian ethics. Of some interest in this regard is the notion of an ethic of care, which is not confined to Christian circles but has been the subject of some debate in recent times.*

1 Christian love

In much Christian literature, perhaps most especially in Roman Catholic theological writings, the word 'charity' has been used to denote the love for God and neighbour commanded by Jesus (John 15: 12) and extolled by St Paul (1 Corinthians 13). In the writings of Aquinas and others, charity (in Latin *caritas*) is also described as the greatest of the theological virtues (see Theological virtues). The more generic term 'love', which is commonly used in the context of erotic relationships and friendship, has been said by many authors to be too imprecise to convey the distinctiveness of Christian love (see Love §2). 'Charity' too, however, is not devoid of ambiguity. In fact, it is most commonly used nowadays to indicate benevolence, beneficence, philanthropy or an organization dedicated to philanthropic pursuits (see Help and beneficence). Some writers have made use of the expression 'charity-love', but, as Leandro Rossi has pointed out (1976), this term, in addition to being too complex and divorced from what is normal, might serve only to combine the ambiguities. The most suitable word, he concludes, is *agapē*. This Greek word is, of course, widely used in the New Testament. Moreover, it would seem to be the preferred term nowadays in theological circles - including Roman Catholic ones. Indeed, Gene Outka goes so far as to say that, in current usage, *agapē* 'is almost uniformly the referent for any alleged distinctiveness in Christian love' (1978: 7).

A mere change of word, however, does not suffice to eliminate all disputes about Christian love. Writing in the 1930s, Anders Nygren claimed that the classical Catholic idea of *caritas*, which stemmed largely from the writings of Augustine, has little to do with specifically Christian love. This is so, he maintains, because, in the Catholic notion, the primitive Christian *agapē* motif is combined with the *eros* motif. *Eros* here means the human desire for union with God. *Agapē*, on the other hand, is the distinguishing mark of Christianity. Christian fellowship with God depends entirely upon God's love (*agapē*). On the human side, there is no way that leads to God. There is only a way for God to come to humans, and that is *agapē*. In other words, there is simply no connection between *agapē* and *eros*. They are totally incompatible. He goes on to say that Christians have nothing of their own. The love they show to others is the love that God has infused into them (Romans 5: 5).

The renowned Protestant scholar Karl Barth (1967) also saw the need to distinguish *eros* and *agapē*. He went on to say, however, that the kind of relationship in which only God was at work and humans were mere channels of divine action could not be described as a covenant relationship, and yet, according to Scripture, that is the true relationship between them (see Barth, K.). The initiative in this relationship is wholly and exclusively on the part of God, but that initiative aims at a correspondingly free human act, not the reaction of a puppet. The Roman Catholic moral theologian Bernard Häring (1979), on the other hand, takes the view that all human love can be redeemed. When, in response to God's *agapē*, believers commit themselves to God, he says, all their prior dispositions, including *eros* and friendship, are gradually transformed, purified and raised to a higher level.

There has been some complaint in recent times that Christian love - whatever we wish to call it and whatever its relationship to *eros* may be - does not figure highly enough in Christian ethics. Referring specifically to Roman Catholic works, and writing in the 1950s, Gérard Gilleman noted that manuals of moral theology had law rather than love as their dominant theme. He therefore sought to establish 'a method of exposition in which charity will play the role of a vital principle, just as it does in the message of Christ and in Christian life' (1959: xxxvi). More recently, some Roman Catholic moral theologians have laid more emphasis than had previously been apparent in

their discipline upon the distinction between personal goodness and the rightness of acts. Personal goodness exists when someone is truly loving (charitable). Mere rightness of acts does not necessarily indicate personal goodness. One could perform an ethically right act for a variety of motives, not all of them loving.

Within Protestantism, attempts to place greater emphasis on Christian love in Christian ethics can be found among some situation ethicists (see Situation ethics). One of the best known is Joseph Fletcher, who holds that principles and rules can be enlightening, but never the deciding factor. That status can only be given to love. In a given situation, one has to decide what is the loving thing to do. Numerous writers have lamented the fact, already noted, that the word ‘charity’ is now used chiefly to denote benevolence rather than Christian love. It could therefore seem surprising that Fletcher should describe Christian love as precisely benevolence. Having noted, however, that such words as ‘benevolence’ and ‘goodwill’ have taken on a tepid meaning, Fletcher goes on to say that ‘*Agapē* goes out to our neighbors, not for our own sakes nor for theirs, really, but for God’s’ (1966: 105).

Whatever one makes of this contention or of Fletcher’s situation ethics in general, the fact remains that, in recent times, the word charity has been used most often to refer to benevolence in a sense that is not specifically theological, or to beneficence. One can hardly claim, moreover, that the reason is purely linguistic - other senses of ‘charity’ having been taken over, so to speak, by *agapē*. Outside the confines of theological circles, the Greek word is seldom encountered.

2 An ethic of care

Moreover, it is claimed by many that, beyond the confines of theological circles, there has been very little emphasis in recent times upon the demands of charity in ethics. Even discussions of philanthropic endeavours such as those aimed at the relief of poverty, it is pointed out, are discussed habitually in terms of justice. Given this state of affairs, recent discussion about an ethic of care has been particularly interesting (see Feminist ethics §1). The debate began with Carol Gilligan’s book *In a Different Voice* (1982). Gilligan had noted that developmental psychology had been based largely on a study of men’s lives. Lawrence Kohlberg’s theory of moral development, moreover, was built on research that involved no females at all. His six stages of development in moral judgment through which he says one should pass in order to achieve maturity in moral reasoning are founded empirically on a study of eighty-four boys whose development he followed for over twenty years. Gilligan noted that groups not included in the original sample rarely reached the higher stages. This was particularly true of women, whose judgments, on the whole, seemed to exemplify Kohlberg’s third stage. At that stage goodness is seen in terms of helping and pleasing other people, and morality is conceived in interpersonal terms. At the ‘higher’ stage four, ‘relationships are’, in Gilligan’s words, ‘subordinated to rules’, while rules are, in turn, subordinated to universal principles of justice at stages five and six (1982: 18). Kohlberg’s notion of maturity derives from a study of men’s lives and, says Gilligan, ‘reflects the importance of individuation in their development’. If, however, developmental constructs are derived from a study of women’s lives, a conception of morality as concerned with care emerges. Moral development is then seen as centred around responsibility and relationships, whereas, when morality is seen in terms of fairness, moral development is tied to the understanding of rights and rules. Gilligan has noted, however, that the care perspective is not confined to women (see Moral development).

An ethic of care does not necessarily involve the specifically Christian concept of charity or *agapē*, but, no doubt, many would be of the opinion that it could, if it were adopted in Christian circles. Whether such charity is involved or not, however, it would seem that both philosophical ethics and specifically Christian ethics might benefit from further debate about Gilligan’s basic idea. Interestingly, as John R. Donahue noted (1977), the biblical notion of justice could be described in terms of faithfulness to the demands of relationships.

Charity, principle of

The principle of charity governs the interpretation of the beliefs and utterances of others. It urges charitable interpretation, meaning interpretation that maximizes the truth or rationality of what others think and say. Some formulations of the principle concern primarily rationality, recommending attributions of rational belief or assertion. Others concern primarily truth, recommending attributions of true belief or assertion. Versions of the principle differ in strength. The weakest urge charity as one consideration among many. The strongest hold that interpretation is impossible without the assumption of rationality or truth.

The principle has been put to various philosophical uses. Students are typically instructed to follow the principle when interpreting passages and formulating the arguments they contain. The principle also plays a role in philosophy of mind and language and in epistemology. Philosophers have argued that the principle of charity plays an essential role in characterizing the nature of belief and intentionality, with some philosophers contending that beliefs must be mostly true. A version of the principle has even served as a key premise in a widely discussed argument against epistemological scepticism.

1 Versions of the principle of charity

The principle of charity is typically taken to be a principle about how to interpret the words and thoughts of others, favouring interpretations that maximize the accuracy and rationality of their utterances and beliefs. There are a variety of more precise formulations of the principle, emphasizing different aspects. Principles of charity also differ with regard to the strength and source of the commitment to charitable interpretation.

Truth and rationality are two dimensions along which one can urge charity. It can be that a person's situation is such that the most reasonable thing for them to believe happens to be false. If there is a question about how to interpret the person, where the choice is between attributing a reasonable but false belief and a true but unreasonable belief, the various versions of the principle of charity will choose differently.

Principles of charity can also differ in strength. The weakest merely recommend consideration of charitable interpretations, leaving open the possibility that in some circumstances one can properly interpret others in ways that make them irrational or mistaken. Moderate positions demand interpreting others as rational or right except in those rare cases in which there are compelling reasons to do otherwise. Stronger versions hold that it is never appropriate to interpret others as irrational or systematically mistaken. It is possible to regard the commitment to charity as merely a contingent but universal truth about the interpretation of humans by imperfect human interpreters or as an a priori requirement about all interpretation. Some versions of the principle are not primarily directives about how to interpret others but are, instead, principles to the effect that intentional states are by their nature rational or accurate so that interpreting others as irrational or mistaken is necessarily incorrect.

2 Charity and critical thinking

In courses on critical thinking (or argument analysis or informal logic), students learn a method for interpreting and evaluating the arguments and assertions that they read and hear. The principle of charity often plays a central role in the methodology taught in such courses. The version of the principle advanced in this context is typically one of the weaker ones mentioned above, recommending that charitable interpretations be favoured, but acknowledging other considerations as well. Advocates of charity differ over the basis for the principle. Some see it as an ethical matter. On this view, being charitable is part of being fair to those with whom one interacts. An alternative view emphasizes a more epistemological and pragmatic basis for being charitable: being charitable best contributes to one's own pursuit of the truth. Interpreting others in ways that make their words less plausible may make it easy to refute them. But interpreting and reflecting on the most plausible interpretation of their words is apt to increase the interpreter's own understanding of the issues addressed. When there is a more plausible and more insightful interpretation available, there is little point in considering a less plausible interpretation of the assertions or arguments of others.

3 Charity and philosophy of mind

Something resembling the principle of charity plays a key role in Daniel Dennett's influential philosophy of mind.

According to Dennett, when we describe a thing as an intentional system (a thing with propositional attitudes), we must take it to be rational. Dennett's claim is not endorsing any of the weaker theses described above. Rather, his claim is about the possibility of explaining or characterizing irrationality in intentional terms. He says of a purported case of irrationality, 'we must descend from the level of beliefs and desires to some other level of theory to describe' the case, since such cases 'defy description in ordinary terms of belief and desire' (Dennett 1982: 66-7). The claim here is not that we are always rational, but just that we cannot give intentional explanations of seemingly irrational behaviour. On Dennett's view, charity is not just a pragmatic, moral or epistemic principle to help guide interpretation. It is an essential part of intentional interpretation. Dennett argues for this partly by appeal to general considerations about belief and other intentional states, partly by appeal to the difficulty he finds in filling out the details of intentional explanations in cases of alleged irrationality.

4 Charity, philosophy of language and epistemology

The most widely explored use of the principle of charity is in discussions of radical translation. W.V. Quine and Donald Davidson are the most influential defenders of the principle in this setting. Quine discusses cases of radical translation - translation in cases in which the words to be translated are those of people in a foreign and unfamiliar culture. He contends that if we come up with a translation scheme that renders their beliefs and utterances regularly silly or mistaken, we will eventually be driven to question our translation scheme and replace it by one that makes more sense of them. Thus, if a person utters a certain sentence when and only when a rabbit passes by, one is to interpret that sentence to mean something like the true 'That's a rabbit', rather than the false 'That's a duck'. Of course, other things the person says might make the latter interpretation best, but then these other things are interpreted as truths, thereby preserving the truth of most of what the person says (see Quine, W.V. §9; Radical translation and radical interpretation).

Donald Davidson defends an account similar to Quine's, but he puts it to a surprising use, developing an influential argument against epistemological scepticism (see Davidson, D. §5). Sceptics deny that we have knowledge, either globally or in some particular domain. Davidson appeals to the principle of charity in an argument against global scepticism. According to Davidson, what the principle of charity really requires is that the interpreter construe the subject's words so that the subject's beliefs mostly match the interpreter's. There's no guarantee of truth here; at best there is a guarantee of agreement. This would hardly worry a sceptic, as Davidson is willing to concede. But his argument has a second stage designed to overcome scepticism. He asks that we imagine an omniscient interpreter who believes all and only truths about the world of some subject. The omniscient interpreter is also bound by the principle of charity, and thus must interpret the subject's beliefs so that they largely match the interpreter's own. Since the corresponding beliefs of the omniscient interpreter are all true, the beliefs of the subject must be largely true. Thus, the nature of interpretation rules out the possibility that any interpretable being has beliefs that fail to be largely true. Hence, any scepticism based on the possibility that one's beliefs are mostly false is ruled out.

Quite a few philosophers have found Davidson's argument questionable, though they have differed over its fundamental flaw. Among the criticisms are these:

(1) The appeal to the omniscient interpreter raises a cluster of complex questions about possibility. Davidson surely does not want to rest his argument upon the assumption that there actually is an omniscient interpreter. Rather, his claim is merely that there could be one. Suppose that assumption is granted. Suppose further that in some possible world the omniscient interpreter interprets someone's beliefs. It may follow that, in that world, anyone interpreted must have mostly true beliefs. But nothing follows about the accuracy of anyone's beliefs in the actual world. Hence, nothing contrary to scepticism about actual humans follows.

There are various ways for Davidson to formulate his argument to try to get around this objection, perhaps the most promising being the following. There may be an omniscient interpreter in some other world who has true beliefs about the actual world and who interprets the beliefs of any individual, *S*, in the actual world. That interpreter is bound by the same rules of interpretation, and thus *S*'s beliefs must largely coincide with the true beliefs of the interpreter. Hence, *S* has beliefs that are mostly true. Critics of this response may doubt the justifiability of assuming that there is a possible interpreter who is (a) omniscient, (b) capable of interpreting *S*, and (c) required to make *S*'s beliefs match the interpreter's own beliefs.

(2) Even if we grant Davidson's conclusion that it is impossible that most of *S*'s beliefs are false, it does not follow that *S* knows much. From the fact that most of *S*'s beliefs are true, and even from the fact that *S* knows this, it does not follow that with respect to almost any individual belief that *S* considers that *S* knows that it is true. Consider the analogy of a lottery in which most of the tickets will win small prizes. One can know that most tickets are winners without knowing of any particular ticket that it is a winner. Similarly, even if *S* knows that most of *S*'s beliefs are true, it may be that there are none (other than that one and its consequences) that *S* knows to be true. Thus, even if sound, Davidson's argument leaves unscathed an extreme sceptical view. Davidson might reply that *S*'s knowledge that *S* is mostly right provides justifying evidence for each of *S*'s beliefs, thereby making each true belief justified, and thus knowledge. This, however, seems to rely on a remarkably low standard for knowledge-level justification.

(3) Much of the interest in Davidson's argument stems from the fact he attempts to draw such an epistemologically significant conclusion from a fact about the nature of radical interpretation. Thus, much of the criticism has focused on the connection between the principle of charity and scepticism. However, the principle itself is not without critics. Indeed, one may well wonder why Davidson thinks charity is essential for interpretation. Surely, in general interpreters do not always have to make their subject's beliefs largely agree with their own: interpreters will have many beliefs about their own home environment, beliefs remote subjects need not share. What may be more plausibly required is that interpreters attribute to subjects beliefs that the interpreters would hold given the subject's evidence. In other words, perhaps in interpretation one must assume that one's subjects respond to evidence in much the way one does oneself. Even this will seem dubious to many. Why, it could be asked, can one not take a subject to be responding erroneously to evidence? But even if this sort of principle of charity is granted, it is doubtful that the desired anti-sceptical conclusion follows. This is because one can grant that another person is responding properly to evidence but is nevertheless massively deceived. Thus, a brain in a vat, or a victim of the Evil Demon, might respond properly to evidence, but still have consistently false beliefs because that evidence is systematically misleading. Hence, a revised, and perhaps more plausible, version of the principle of charity requires only that interpreted subjects respond properly to evidence. This leaves open the possibility of massive deception and thus does not yield the anti-sceptical result.

(4) Facts about how best to interpret others are in general logically independent of how those others actually must be. It would therefore be surprising if a requirement that we interpret others so as to make them not globally mistaken could yield the conclusion that they cannot actually be globally mistaken. It is, therefore, noteworthy that in some descriptions of his argument against scepticism, Davidson presents it in a way in which the principle of charity is not fundamentally a principle about how to interpret others but rather a principle about what intentional states must be like. He writes, 'What stands in the way of global skepticism is, in my view, the fact that we must, in the plainest and methodologically most basic cases, take the objects of a belief to be the causes of that belief. And what we, as interpreters, must take them to be is what they in fact are' (Davidson [1983] 1986: 317-18). The idea here is that the content of a belief is determined by the external states that cause it. Thus, for example, the belief that a subject has when undergoing a certain sort of sensory stimulation has as its content the external state regularly causing that sort of stimulation. This is a causal theory of meaning or content. On this view, it is the nature of language and belief that requires that our beliefs and utterances be largely true. This makes charitable interpretation appropriate, but only because independent facts about belief and language imply that uncharitable interpretations are always inaccurate.

Whatever the nature and role of the principle of charity in the version of Davidson's argument just described, the argument is not without its critics. Some dispute the causal theory of meaning upon which it depends. Others contend that even if it is sound, Davidson's argument does not really refute scepticism. They argue that even if it shows that that we know that our beliefs are true, we can still fail to know the content of our beliefs. This is because we cannot tell which external states are systematically causally connected to our beliefs. For example, it is possible that a particular sort of belief is systematically connected either to the presence in one's visual field of a certain kind of object or to a certain sort of computer state in the computer to which one's brain is connected. Davidson's view apparently implies that the content of the belief depends upon which sort of cause it has, and, the critics contend, Davidson has not shown how one can know which sort of cause one's belief has. This seems to leave intact a radical form of scepticism. Whether this objection succeeds depends upon whether there is room within Davidson's view for some sort of privileged access to the contents of one's beliefs.

Charleton, Walter (1620-1707)

The physician Walter Charleton was the first to introduce Epicurean atomism into England in the form advocated in France by Gassendi. Charleton's version of atomism, although largely derivative, was nevertheless influential. Together with his advocacy of a Christian hedonism, it helped to make both atomism in natural philosophy (with its associated mechanistic account of nature) and utilitarian theories in ethics acceptable to such thinkers as Robert Boyle, Isaac Newton, John Locke and others associated with the foundation of the Royal Society, of which Charleton was himself an active early member.

Walter Charleton was a physician who served both Charles I and Charles II, but his interests were always broader than medicine. He entered practice after studying at Magdalen Hall, Oxford, under John Wilkins, also one of the founders of the Royal Society. Charleton's quick rise to fame made him enemies, which in part explains his sad decline to poverty in later years after serving as President of the College of Physicians from 1689-91.

Charleton's major philosophical writings were two books on the philosophy of Epicurus and two on central religious themes (the absurdity of atheism and the immortality of the soul). But it is important to appreciate that although he clearly saw himself as an exponent of a modified Christian version of the philosophy of Epicurus, in which he substantially followed in the footsteps of Gassendi, he was also almost equally influenced by the philosophy of Descartes. In each of them he found a commitment to mechanism as the basic explanatory concept for an understanding of nature, together with a theism which rejected a materialist account of the mind.

In his *Physiologia Epicuro-Gassendo-Charletoniana: or a Fabrick of Science Natural upon the Hypothesis of Atoms* (1654), Charleton openly follows the radical natural philosophy espoused by Gassendi in considerable detail, even though its full exposition was not available until 1658, after Gassendi's death. The *Physiologia* offers a detailed and comprehensive account of matter and its properties in terms of atoms and motion. Although close to Epicurus, it is much fuller than any of the extant writings. Contrary to the traditional teaching of the Schools, the motion of atoms in the void is argued to be the basic explanation for all the phenomena of nature and of our awareness of those phenomena through sensation. In so doing, Charleton argues for the distinction between primary and secondary qualities, made famous by Boyle and Locke later in the century, and presents accounts of light, colours, sounds and other phenomena within the atomic model. Charleton makes no claim to absolute certainty - it is the *hypothesis* of atoms that he expounds. But he makes a very good case for the mechanical account of nature from within the new learning associated with Bacon, Descartes, Gassendi and even his friend Thomas Hobbes, although he never accepted Hobbes' materialism.

Charleton had made clear his hostility to a full blown-materialism in *The Darknes of Atheism dispelled by the Light of Nature* (1652). A similar position was also presented in the later *Immortality of the Human Soul demonstrated by the Light of Nature* (1657). In these works Charleton follows Descartes rather than Gassendi, not only in his proof of God where he gives (with full acknowledgement) the causal argument offered by Descartes in the third Meditation, but also in a sharp dualism between mind and matter. The soul is a substance perfectly distinct from that of body, he claims, and it is endowed with immortality by the character of its essence. He follows Descartes, too, in holding that the idea of God is innate.

In drawing on Descartes' philosophy Charleton makes it clear that he wishes to distance himself from all those aspects of Epicurus that might be supposed to support atheism. Like Gassendi and Descartes he was keen to make his account of the new philosophy not just compatible with, but actually supportive of a Christian theology. At the same time he was quite sure that standard criticism of Epicurus was far too severe, as he made clear in the Introduction to his edition of Epicurus' moral philosophy, *Epicurus's Morals* (1655). Rather than being, as he was so often depicted, an advocate of impiety, gluttony and drunkenness, Epicurus was, Charleton urged, a great master of temperance, sobriety, continence and fortitude. Charleton is quite prepared not only to admit but to argue that Epicurus was wrong on several fundamentals. His three cardinal errors were his rejection of both the immortality of the soul and the worship of God, and his acceptance of suicide. There were, nevertheless, extenuating circumstances which went some way towards excusing Epicurus these undoubted errors, principally his living in a pagan country before the advent of Christianity. Granted the errors, Charleton, makes clear that he believes Epicurus has much to teach us about happiness and how it may be best obtained.

In all his writings Charleton is careful not to appear dogmatic. Nor was he ever an uncritical supporter of those who influenced him. This is especially true of his later writings. In his *Natural History of the Passions* (1674), for example, Charleton takes Descartes to task both for his bad anatomy (Charleton was an undoubted expert on anatomy) and for his inadequate explanation of the connection between mind and body.

Charleton died in poverty in Nantwich. His major influence was through the *Physiologia*, which introduced many English speakers to atomism, including the young Isaac Newton. His other works contributed to that assault on traditional teaching and the adoption of the mechanistic and hedonistic philosophies that came to dominate the eighteenth century.

Charron, Pierre (1541-1603)

Pierre Charron was a French Catholic priest of the late sixteenth century who used Montaigne's sceptical thought, which he presented in didactic form, in order to refute Calvinists, non-Christians, and atheists. He advanced a fideistic defence of religious thought which was based on accepting complete scepticism while appealing to faith alone as the source of religious knowledge. His De la Sagesse (On Wisdom) (1601) is one of the first significant philosophical works to be written in a modern language. It is also one of the first modern works to set forth a naturalistic moral theory independent of religious considerations, and based primarily on Stoic ideas. Charron's views were extremely popular in the seventeenth century, and they influenced many sceptically inclined thinkers in France and England. His sceptical 'defence' of religion was regarded as insincere by some of the orthodox theologians, but other important religious thinkers defended him.

1 Life and works

Pierre Charron, philosopher and theologian, was born in Paris, one of twenty-five children. He studied Greek, Latin and philosophy at the Sorbonne, and then, after possibly studying law at Orleans and Bourges, went to the University of Montpellier from which he received the degree of Doctor of Law in 1571. After practising law unsuccessfully for a few years in Paris, he turned to theology and soon became renowned as a preacher and theologian. He was chosen by Queen Marguerite to be her regular preacher, and Henri IV, even before his conversion to Catholicism, often attended his sermons. He then became lecturer in divinity in various cities in the south of France, and canon and official teacher of the church of Bordeaux. Despite his great success he desired to give up worldly activities and to join a cloister, but he was turned away by two orders because of his age (forty-eight at the time). The most important event in Charron's life was his friendship with Michel de Montaigne (though doubt has been cast on its extent). After Montaigne's death in 1592, Charron demonstrated his immense debt to Montaigne by presenting the union of scepticism and Catholicism in his writings.

Charron's first work, *Les Trois Veritez (The Three Truths)* (1594), was an apologetical work of theology which attacked Calvinists in particular. His major philosophical work, *De la Sagesse (On Wisdom)*, appeared in 1601, as did his Discours chrestiens (Christian Discourses). His final work, *Le Petit Traicté de la sagesse (Little Treatise on Wisdom)*, was written in 1603 and published posthumously in 1606. All of his works were very popular, and were often republished during the seventeenth century. *De la Sagesse* was most influential in disseminating sceptical ideas and arguments in the philosophical and theological discussions of the time.

There were several serious efforts to refute, reject and even suppress Charron's sceptical views. He was attacked by the Jesuit, François Garasse, who accused him of providing a breviary for libertines, and by the Protestant medical doctor, Pierre Chanet, among others. He was defended by the *libertins érudits* Guy Patin, Gabriel Naudé, François de La Mothe Le Vayer, and Pierre Gassendi, as well as by some French leaders of the Counter-Reformation (see Libertins). Pierre Bayle considered Charron a fine exemplar of Christian fideistic thought.

2 Theological thought

In his first work, *Les Trois Veritez*, Charron sought to undermine Calvinism by sceptical means. The three truths which he considered, that God exists, that Christianity presents the correct view of God, and that Catholicism is the true presentation of Christianity, are each supported by attacking the opponents in a negative manner rather than by presenting positive reasons for accepting the truths. Although most of the enormous work is devoted to the third truth, it begins with a brief discourse about knowledge of God, in which a scepticism is developed about the possibility of human beings having knowledge in this area. Human rational capacities are so restricted and unreliable that it is doubtful that humans can know anything in either the natural or supernatural realms. Charron then joined his sceptical claims about the inadequacy and unreliability of human knowledge to the contention of the negative theologians that God is unknowable because his nature is infinite, and thus surpasses all human attempts to define or delimit it. Hence we cannot rationally know what he is, and as a result, the greatest philosophers and theologians know just as much or just as little about God as do the humblest persons. What we know is only what God is not. So, Charron said, 'the true knowledge of God is perfect ignorance about him'.

Charron's combination of negative theology and scepticism was then used to attack the claim of the atheist who denies that God exists. Such a denial, Charron argued, is presumably the consequence of a definition of God from which absurd or contradictory conclusions are drawn, but any such definition can only be the result of a human attempt to measure divinity by human means, an attempt which has no value, since atheists do not and cannot know what they are talking about.

Finally Charron argued negatively that it is unreasonable not to believe that God exists, and not to believe that Christianity is the correct statement of God and his role, and not to believe that Catholicism is the right form of Christian belief. He claimed that his opponents, especially the Calvinists of the day, argue on the basis of views derived by means of weak and miserable human capacities, and then use these unreliable results to measure divine truths.

3 Sceptical philosophy

Charron's sceptical defence of faith was elaborated in *De la Sagesse* and *Le Petit Traicté de la sagesse*. He claimed that since human beings can only discover truths by means of revelation, morality should be based on following nature except when it is guided by Divine Light. This view was first developed by setting forth Montaigne's scepticism in an organized didactic form. We must begin by knowing ourselves, which involves knowing the limits of what we can in fact know. Charron presents the traditional sceptical doubts about sense knowledge. Do we have the requisite sensory capacities to gain genuine knowledge? Are we able to distinguish illusions and dreams from veridical experiences? And can we ascertain which of our many varied sense experiences actually correspond to some objective state of affairs?

Charron then turned to questions that can be raised about our rational capabilities. He contended that we possess no certain or adequate criterion for distinguishing truth and falsehood. We in fact believe what we do as the result of our passions and of social pressures on us, rather than on the basis of reasons and evidence. We actually function as beasts do, rather than as rational beings. Hence we should accept Montaigne's claim that we possess no genuine principles unless God has revealed them to us. Everything else is just dreams, smoke, or illusion.

In the second book of *De la Sagesse* Charron set forth a discourse on method as a way of avoiding error and discovering truth in the light of the human situation. The Charronian method anticipates that of Descartes. First, one should examine each question freely and dispassionately. Next, one should keep prejudice and emotion out of all decisions. After that, one should develop a universality of mind. Finally, one should reject any decisions which are doubtful in even the slightest degree. This sceptical method or method of doubt was, Charron declared, of greater service to religion than any other possible method. If we followed it, we would reject all doubtful opinions until our minds became 'blank, naked and ready' to receive divine revelation on the basis of faith alone. So, Charron insisted, the complete sceptic will never be a heretic, for the sceptic, having no opinions, cannot have the wrong ones. On the other hand, if it pleases God to give the sceptic any information, he will possess true knowledge.

Until the sceptic receives any revelation, he ought to live according to a provisional morality. This is described in the third and final book of *De la Sagesse*, which sets forth Charron's theory of natural morality based on ancient sceptical and Stoic views. Without divine guidance the best one can do is live naturally as a Stoic sage or a noble savage. Here Charron is one of the first modern philosophers to set forth a moral theory independent of religious considerations.

At the time, some readers saw Charron's work as a basic didactic presentation of Pyrrhonian scepticism that challenged traditional philosophical claims to knowledge as well as religious views. By so doing, these readers believed, Charron was preparing the basis for a completely naturalistic view of human nature and conduct. However, Charron averred that *De la Sagesse* contained only part of his theory, namely that which deals with the human situation seen completely apart from divine guidance. When one considers the views in his different works taken as a whole, together with his ecclesiastical career and the religious sentiments that appear in his Discours chrestiens, one can find evidence for the case that Charron was a sincere fideist who propounded scepticism as a way of destroying those whom he saw as the enemies of the true faith, while preparing others for salvation by God's actions. Whatever his true views, Charron greatly influenced the so-called *libertins*, and his ideas, as interpreted by them, provided some of the basis for irreligious naturalism in the Enlightenment.

Chartres, School of

In the first half of the twelfth century, the most advanced work in teaching and discussion of logic, philosophy and theology took place in the schools attached to the great cathedrals. Chartres was undoubtedly one of the more important of these schools, and Gilbert of Poitiers and Thierry of Chartres were certainly connected with it. To some historians, Chartres was the *great intellectual centre of the period, and the greatest achievement of early twelfth-century thought was a brand of Platonism distinctive of this school. However, this view has been challenged by scholars who stress the pre-eminence of Paris, where the schools emphasized logic.*

1 Who taught at Chartres?

When Clerval (1895) first claimed the particular importance of early twelfth-century Chartres as an intellectual centre, he believed that he could point to four outstanding figures who had been schoolmasters there. First, there was Bernard, described as teaching at Chartres in John of Salisbury's *Metalogicon* (see John of Salisbury); Clerval identified him with Bernard Silvestris (Bernard of Tours), author of the *Cosmographia*, a prosimetrum recounting the creation of the world and of man in terms closely reminiscent of Plato's *Timaeus*. Second was the polymath Thierry of Chartres and third was Gilbert of Poitiers, one of the leading theologians of the mid-twelfth century. Finally, most scholars of Clerval's time believed that William of Conches, the grammarian and commentator on Platonic texts, was also a teacher at Chartres, although more recent research has cast doubt on various aspects of this claim.

The Bernard described in the *Metalogicon* - who was probably born *circa* 1060, and is mentioned in charters as master of the school at Chartres between 1114 and 1119 and as Chancellor between 1119 and 1124 - is no longer identified with Bernard Silvestris, who taught at Tours in the mid-twelfth century and whose only link with Chartres was his friendship with Thierry. The Chartrian Bernard was a grammarian, interested in Priscian and the theory of grammar as well as in expounding classical Latin tests. Although a commentary on Plato's *Timaeus* has been attributed to him with some plausibility, he was not, like the author of the *Cosmographia*, one of the great writers of the time.

The distinction between Bernard of Chartres and Bernard Silvestris is now accepted by all historians. The relation of other leading teachers to Chartres remains controversial: Sir Richard Southern (1970) has been the leading sceptic, while Edouard Jeauneau (1973), Peter Dronke (1969) and Nikolaus Häring (1974) have argued for the importance of Chartres. No one queries that Thierry ('the Breton' or 'of Chartres') was linked with Chartres, where he became Chancellor in about 1142. However, it is questionable how much teaching he did there; he is also known to have taught John of Salisbury on the Mont Sainte Geneviève in Paris in 1136-8. Where was his teaching predominantly based? A similar question applies to Gilbert of Poitiers, who was a canon of Chartres in 1124 and chancellor there from 1126 to 1137. Gilbert certainly taught in Paris, and one student mentions attending his lectures both at Paris among an audience of three hundred, and at Chartres in an audience of only four. Does this mean that Chartres was a scholastic backwater, or rather (as Dronke has argued) that Gilbert reserved his most advanced teaching for Chartres?

The connection of William of Conches with Chartres is even more problematic. He very probably studied at Chartres under Bernard and is regarded by John of Salisbury as a continuer of Bernard's approach. Jeauneau has found a few remarks in his work which might hint that he was himself teaching at Chartres, and an unclear and much discussed passage in John of Salisbury's *Metalogicon* (II.10) can be argued to support this surmise. However, this hardly constitutes solid evidence for placing him at Chartres, and there is much to recommend Southern's final view, that William taught neither at Paris nor at Chartres. In sum, Chartres may well have been a more important scholastic centre in the first half of the twelfth century than Southern allows, but there is no denying the pre-eminence of Paris in almost all branches of learning from about 1110 onwards.

2 'Chartrian Platonism'

The dispute about the school of Chartres has gone beyond the merely factual questions of who taught where, to become a debate about the very nature of twelfth-century thought. Many modern supporters of the school of Chartres hold that, in Dronke's words, it stands for 'what is freshest in thought, richest and most adventurous in

learning, in northern Europe, in the earlier twelfth century' (Dronke 1969: 117), and some have suggested that 'Chartres' should be understood less as the name of a place where certain masters taught and more as the label for a distinctive brand of Platonism which was followed by masters such as Thierry, William of Conches, Gilbert of Poitiers and Bernard Silvestris.

Southern disputes this. In his first attack on the idea of a school of Chartres, he wrote of Bernard (of Chartres), Thierry and William of Conches that 'all their thoughts were old thoughts' (Southern 1970: 83). More recently, he has refined his criticisms. The Platonism of the masters who are described as 'Chartrian' was, he suggests, a very scholastic Platonism. It did not involve adopting, knowingly or instinctively, Plato's underlying positions or attitudes, nor some special 'poetic Platonism', but centred rather on the close scrutiny of the one work of Plato's they know, the *Timaeus* in Calcidius' partial translation. The 'Chartrian' scholars, he says (Southern 1979: 10), regarded Plato as an authority on 'the primitive organization of the elements of the universe' and used him not to reach a 'philosophical Platonism' but as 'a contribution to the vast jig-saw puzzle of universal knowledge about the origin of the world'. Such an authority was important as a doorway, but was quickly left behind when more scientific knowledge became available, especially from Arab sources. The 'Chartrian' scholars are better understood, he urges, 'by being freed from the school of Chartres and placed in the wider setting of a common scholastic enterprise' (Southern 1979: 40).

Powerful though it is, Southern's argument has some serious weaknesses. It overlooks the close link, in the work of Bernard of Chartres, William of Conches and Bernard Silvestris, between the study of grammar (which included both the interpretation of classical texts and the theory of grammar, based on Priscian) and what we would now call science. The breaking of this link in the course of the twelfth century should not be seen straightforwardly as scientific progress, but as a fundamental shift in assumptions and methods. Moreover, Southern fails to bring out an important peculiarity shared by at least three of these masters. Unlike most of the leading teachers of their time, Bernard of Chartres, William of Conches and Bernard Silvestris apparently remained arts masters and did not venture into sacred doctrine at all. Further, none of them seems to have been very interested in logic, the area to which (apart from theology) most twelfth-century masters gave the greatest attention (see Logic, medieval). Thierry fits this pattern only partly, since he did write about the Trinity and the creation and seems to have been interested in logic. Gilbert of Poitiers fits it not at all, conforming rather to the more usual twelfth-century mould of the logician who goes on to write theology. Perhaps what the enthusiasts for the school of Chartres have hit upon, half unconsciously, is a group of twelfth-century masters (working in various centres) who rejected the pattern and priorities of intellectual life which were becoming the norm and who, in their lifelong dedication to the arts as opposed to theology, might be seen as forerunners of late thirteenth-century arts masters such as Siger of Brabant and Boethius of Dacia.

Chatton, Walter (*c.*1290-1343)

Chatton was an English philosopher and theologian who developed a detailed critique of the work of William of Ockham, causing the latter to revise some of his earlier writings. Chatton was also at times an opponent of Peter Aureol and Richard of Campsall; he generally, though not always, followed John Duns Scotus and responded to his critics. He is known also for his writings on physics, where he held views in line with those of Pythagoras and Plato, and on the Trinity, where he was strongly attacked by Adam Wodeham.

The English Franciscan philosopher and theologian Walter Chatton was born in the village of Catton, near Durham, around 1290. He was a contemporary of William of Ockham and Adam Wodeham at the Franciscan custodial school in London from 1321 to 1323. There he delivered his *Reportatio* lectures on all four Books of the *Sentences* of Peter Lombard, in preparation for his later *Lectura* on the *Sentences* at Oxford sometime between 1324 and 1330 (most likely in 1328-30). He was one of the examiners of the works of Durandus of Saint-Pourçain and Thomas Waleys at the papal court in Avignon, and is believed to have died there in 1343.

Chatton was such a detailed critic of Ockham that it is impossible to follow many of the arguments in the latter's *Quodlibets* without having Chatton's *Reportatio* at hand. Ockham's famous razor was sharpened partly in response to Chatton's critique. Its early formulation, 'Beings should not be multiplied without necessity', was challenged by Chatton, who counters with an anti-razor that he calls 'my proposition': 'When a proposition is made true by things, if two things are not sufficient for its truth, then it is necessary to posit a third, and so on.' In response, Ockham in his later works reformulates his razor to say: 'When a proposition is made true by things, if two things are sufficient for its truth, then it is superfluous to posit a third, and so on.'

Chatton also attacked Ockham's view of concepts, at least the view Ockham held in the first redaction of his *Sentence* commentary, where he defends the *fictum* theory, which holds that the concept does not exist in the mind as in a subject but only has the reality of an object created by an act of understanding. Chatton himself held the *intellectio* theory, which contends that the concept is nothing else but the very act of knowing. Such an act of knowing is a true quality existing in the soul as in a subject, and is also a natural sign of the object that is immediately understood by means of it. Ockham not only did not despise Chatton's critique of the *fictum* theory, he incorporated his opponent's *intellectio* theory into his later treatments of concepts, at first reducing the *fictum* theory to a 'less probable' opinion and finally abandoning it.

The Ockham-Chatton exchange, however, is not limited to the period when both were in London. In discussing the dependence of a second cause on the first cause in essentially ordered causes, Chatton in his *Lectura* defends Duns Scotus' position against Ockham's challenges, quoting verbatim from Ockham's last philosophical work, the *Quaestiones in libros Physicorum Aristotelis(Questions on Aristotle's Physics)*, probably written at Oxford about 1324.

In dealing with his own questions concerning Aristotle's *Physics*, Chatton is known especially for joining the early fourteenth-century minority including Henry of Harclay, Gerard of Odo and Nicholas Bonet, thinkers who opposed Aristotle's claim that continua cannot be composed of indivisibles. Although Chatton had contemporary allies among the atomists, he seems to be alone in holding that continua are composed of finite numbers of indivisibles. Thomas Bradwardine, in his *Tractatus de continuo (Treatise on the Nature of a Continuum)*, makes Chatton a follower of Pythagoras and Plato, who held the same position (see Aristotelianism, medieval; Platonism, medieval).

Besides Ockham, Chatton had a number of other debating partners. When Peter Aureol attacked Duns Scotus' theory of the univocity of being, Chatton came to its defence. Aureol attacked Duns Scotus for claiming that we can have a univocal concept of being, a concept that is predicable in the same sense both of God and of creatures. Scotus achieved this univocal concept at a price, since his concept of being leaves outside its ambit the modes 'infinite' and 'finite' which, if they were included, would impede 'being' from being predicable both of God and of creatures. Chatton grants this objection, but considers it irrelevant. If Aureol, he argues, wants to include modes and differences in his concept of being, then 'being' becomes a most general concept of all that is opposed to nothing, and this is merely a logical and not a metaphysical concept. It is the latter, according to Chatton, that

Scotus had in mind (see Duns Scotus, J.).

Richard Campsall became Chatton's opponent when he argued that intuitive and abstractive cognition are not really distinct, 'since numerically the same knowledge is intuitive when the object is present and abstractive when it is absent, because plurality should not be admitted without necessity.' Against this position, Chatton raised twelve difficulties and then refuted Campsall by appealing to his anti-razor, arguing that it is not impossible that God conserve in existence the intellect with its abstractive cognition and make the object present without the intellect grasping it as present. Thus for the proposition 'He sees that object' to be true, it is not enough to have the intellect, its abstractive cognition and the object present. A distinct thing has to be added: intuitive cognition.

Chatton clashed with Campsall also over the logic involved in statements of non-identity related to the Christian teaching on the Trinity. Chatton's own treatment of the Trinity had its logical and metaphysical problems, turning the divine essence into a collection of persons. He was severely ridiculed and criticized for such Trinitarian views by Adam Wodeham, who quite likely was the student who wrote down Chatton's *Reportatio*. In the margin of Chatton's text, Wodeham wrote: 'In all this discussion the report is not in accord with the mind of the speaker. Nor is there any wonder, since when the author said these things he was not quite sane. Later on, he thought things out better and had another go at it. And then the reporter naturally expressed things in a better way' (*Lectura secunda* I, 13*, n.28). Wodeham was Chatton's chief critic, often accusing him of misunderstanding or misrepresenting Ockham, or of accepting Ockham's views but pretending, by petty quibbles, that he was differing. Despite Wodeham's frequent attacks on him, however, the influence Chatton had on both Ockham and Wodeham shows his philosophical importance.

Chemistry, philosophical aspects of

Chemistry, like all theoretical sciences, is deeply rooted in philosophical inquiry. Early Greek atomism was a response to Parmenides' argument that the very concept of change is unintelligible. Aristotle in turn argued that a vacuum is impossible and proposed that qualitative change could be better understood in terms of four elements and an underlying prime matter.

During the Arabic and Latin Middle Ages, philosophical commentaries on the nature of materials were brought into juxtaposition with the practical arts of the alchemist, miner and pharmacist. As chemical speculations became more closely connected to observations during the time of the Scientific Revolution, natural philosophers became more and more interested in the methodological aspects of chemistry. Galileo and Locke tried to clarify the relationship between primary and secondary qualities. Boyle struggled to understand how the selective affinities so characteristic of chemical reagents could be explained within the framework of Descartes' mechanical philosophy. Lavoisier's textbook was organized around principles drawn from philosophes *such as Condillac.*

As chemistry became an autonomous science, chemists turned less often to philosophy as a source of theoretical inspiration. However, they frequently appealed to philosophies of science in order to defend their own theories or criticize those of their opponents. The so-called 'atomic debates' amongst chemists in the British Association during the 1860s were primarily disputes about the epistemological legitimacy of appeals to unobservable entities. Many of the same issues were taken up at the end of the century by Ostwald, Mach and Duhem.

Logical empiricists in the twentieth century have often turned to chemistry as an example of the successful reduction of a secondary science to physics. Thus, it is claimed that the laws of classical thermodynamics, expressed using concepts such as enthalpy and entropy, can be derived from the laws of statistical mechanics describing the motions of particles. The details of this purported derivation have been questioned. Even more controversial is the attempt to derive accounts of the chemical bond and the shape of molecules from the first principles provided by quantum mechanics.

1 Early concepts of atoms and elements

To a modern student of chemistry there seems to be no tension between the concepts of atom and element. The periodic table of the elements illustrates how the chemical properties of a simple substance such as sulphur can be related to the physical properties of the atoms of which it is composed, especially its atomic number. Historically, however, there has often been conflict between atomic approaches and research programmes that talk about elements. Examples of the opposition already appear in pre-Socratic cosmological theories about the origins and composition of the world. The typical features of classical atomic theories are present in the fragmentary accounts we have of Leucippus and Democritus (fifth century BC): the world is composed of atoms moving in a void (see Atomism, ancient). The atoms themselves are unchanging, indivisible bits of matter which differ from each other only in size or shape. The processes we observe around us are the result of changing groupings or arrangements of atoms; the qualitative aspects of experience are the results of their collisions with the atoms of our soul or mind. However, Democritus is very explicit that we cannot expect to have knowledge of qualities.

> By convention are sweet and bitter, hot and cold, by convention is colour; in truth are atoms and the void. …There are two forms of knowledge, one genuine, one obscure. To the obscure belong all of the following: sight, hearing, smell, taste, touch.
>
> (Kirk and Raven 1962: 422)

The atomistic tradition was continued by Plato who, in the *Timaeus*, gave an elaborate geometrical account of atoms in terms of the five regular polyhedra (see Plato §16). In *The Nature of Things*, Lucretius provided speculative corpuscular explanations of everything from evaporation to sexual attraction, but in part because of its historical connections to Epicurean moral philosophy, atomistic theorizing became theologically suspect and was not further developed until the rise of modern science (see Epicureanism §§3, 12).

The dominant theory of matter was Aristotle's sophisticated account of the four elements - earth, air, fire and water (an account earlier developed by Empedocles). Aristotle posited an underlying substratum of prime matter that could neither be created nor destroyed. On it were impressed various combinations of the four fundamental

qualities, the hot or the cold, the wet or the dry. The four elements could be transmuted into each other. For example, by adding more warmth to water (formed from the cold and the wet) one could change it into air (characterized as the hot and the wet) (see Matter §1).

In trying to explain the multiplicity of properties which we actually observe, Aristotle associated additional qualities with each element. Thus softness and ductility and a bland taste are characteristic of water. Brittle materials are earthy, while sour or spicy foods contain fire. Not only do ordinary materials contain varying proportions of the elements, they also differ in how intimately the parts are combined.

Although there are places where Aristotle seems to presuppose a sort of conservation law for his qualities, there are also passages in which he says that the more potent properties can completely transform the weaker. Thus if a great quantity of water is added to wine, in the end the water will actually convert the wine into water. In a similar way, Aristotle says, living things can transform food into flesh and bone (*De generatione et corruptione* I 5). The Aristotelian system thus provided the philosophical foundation for alchemy (see Alchemy).

2 Corpuscles, forces and conservation

Greek atomism had postulated that all processes could be understood as the result of collisions between, and regroupings of, invisible particles, but it had very little to say about how or why the atoms moved or what caused them to cohere into relatively stable clusters. Both of these deficiencies were addressed by the theories of motion developed in the seventeenth century. Although Descartes rejected the possibility of a vacuum, his programme of explaining all natural phenomena in terms of corpuscles moving in accordance with laws of inertia and collision was otherwise a continuation of the classical approach. Like Epicurus and Lucretius, Descartes wrestled with phenomena - colour, patterns of iron filings round a bar magnet, and physiology - which seemed particularly recalcitrant to mechanical explanations (see Descartes, R. §11).

Isaac Newton not only corrected the Cartesian laws of motion, he also revolutionized its ontology. The universal law of gravitation plus his three laws of motion gave a complete account of the movements of both heavenly bodies and middle-sized terrestrial objects such as projectiles. Newton was convinced that additional forces, each with a corresponding force law, would be needed to explain behaviour at the atomic level. Thus, he postulated a repulsive force varying inversely with the distance between nearest neighbours to explain the ’spring’ in air which makes it resist compression. And in the famous thirty-first query of the *Opticks* Newton suggests that a variety of cohesive forces acting at short range may be needed to account for the ’sociability’ of chemicals for each other. John Locke tried to give a philosophical account of how the world of sense experience with its rich diversity could be reduced to the ’solid, massy, hard, impenetrable, moveable particles’ proposed by Newton which varied only in size, figure and velocity (see Locke, J. §4; Primary-secondary distinction §1).

Even if the relationship between primary and secondary qualities could be clarified to the satisfaction of philosophers, there still remained the difficulty of how working chemists, who dealt with what British schoolchildren came to know as the science of ‘bangs and stinks’, could relate atomic models to the practical problems of describing the properties and reactions of materials in the laboratory. And as chemists made progress in classifying materials according to their reactivities into, for example, acids, bases and salts or metals, calces and reducing agents, they found it more useful to think in terms of underlying elements or principles characterized in terms of their qualitative chemical natures, instead of the geometrical properties of corpuscles. The chemists working in this tradition, while not denying the possibility of underlying atoms, nevertheless ignored them when theorizing about chemical reactions.

Aristotle had accepted the Parmenidean axiom that a persisting underlying reality was a prerequisite for understanding change, and in his system prime matter is conserved. However, most of the things chemists were interested in, such as the elements themselves, were not conserved on Aristotle’s account. By the eighteenth century there was a concerted effort to find a small fundamental number of chemical elements or principles which were conserved.

For the atomists, of course, conservation was built into the system - atoms are by definition invariant - and they prided themselves on the clarity and parsimony of their list of primary properties, size, figure, and so on. But atomists also had no way to limit or predict how many different types of atom there should be.

Those who postulated elements defined in terms of qualities permitted themselves a richer set of basic properties, but placed much stricter limits on the number of different kinds of element. Stahl, for example, retained a version of the four traditional elements but added to them the three ’earths’ proposed by Becher: the saline earth (the principle of acidity), the sulphurous earth or phlogiston (the principle of inflammability) and the mercurial earth. Although originally called ’earths’, these chemical principles were characterized by their great activity and, as became evident in later variants of the phlogiston theory when phlogiston was assigned a zero or even negative weight, their material nature was sometimes in doubt. But Stahl was adamant that the principles were conserved.

In his treatises on both the sulphurous and saline principles, Stahl extolled what he calls the joint method of analysis and synthesis. The standard chemical practice of determining the composition of a complex material by analysing it into its simpler constituents is fallible because either some of the analysands may be lost or something may be inadvertently added. Stahl recommends that chemists should ’complete the proof’ by resynthesizing the material in question. Thus he believed that he had proved that sulphur contained phlogiston because he could prepare it using charcoal (a major source of phlogiston). It is an irony that Stahl’s system was eventually rejected on the basis of Lavoisier’s famous experiments in which the red calx of mercury was first analysed, thereby forming oxygen gas, and then resynthesized from the gas and metallic mercury.

Lavoisier’s textbook of 1789 presents a list of dozens of elements, most of which are familiar to us today, and emphasized that not only mass but also the quantity of each individual element is conserved in all reactions. Lavoisier also gives the concept of element an operational definition - we are to take as elements those simple substances which cannot be further broken down in the laboratory. And, unlike Stahl, Lavoisier stressed the importance of tracking what happens to elements in reactions by weighing products and reactants. However, Lavoisier was not entirely consistent in his approach: two imponderable fluids which cannot be isolated, light and caloric, are the first elements on his list.

3 Positivism and nineteenth-century atomism

In 1808 Dalton provided a link between the atomistic research programme and Lavoisier’s descriptive chemistry. Each material element on Lavoisier’s list consisted of atoms of a characteristic weight surrounded by caloric. The relative weights of atoms could be calculated from empirically determined combining weights. At last there was a direct way to specify one of the primary properties attributed to atoms. Over the next century a great deal of experimental work went into determinations of atomic weights and molecular formulae.

However, Dalton’s atomic theory provided no conceptual resources for explaining what held atoms together when they formed compounds. Unlike earlier ’hooks and eyes’ speculations, Dalton pictured all atoms as spherical. And their effective volumes seemed to reflect how much caloric surrounded them rather than their intrinsic sizes. Caloric itself caused atoms to move apart, thus only heightening the mystery of the nature of chemical bonding.

Boscovich (1763) had developed Newtonian matter theory by drawing speculative graphs which showed alternating attractive and repulsive forces as a function of distance from the nucleus (see Mechanics, classical), but no one had any idea of how to relate these diagrams to chemical reactivities. Most puzzling was the fact that the reactivity of a material depends on its ‘sociability’ or compatibility with other reactants. Thus, as the alchemists were very aware, although gold is in general less reactive than silver, aqua regia will dissolve gold much more readily than it will silver. Aqua fortis, on the other hand attacks silver but not gold. Furthermore, the extent to which chemicals ’elected’ to combine was sometimes a function of temperature or concentrations. It was difficult to fathom how Boscovichean forces could depend on such variables. This was one major reason why Kant concluded that chemistry would never be a theoretical science founded on universal mathematical laws. But after the discovery of electrochemical phenomena, philosophically minded chemists hoped that chemical affinities could be explained in terms of electrical attractions. After all, in voltaic cells electricity was produced from chemical reactions while in electrolytic cells electricity could be used to decompose complex bodies back into their elements. Berzelius’ ’dualistic theory’ proposed that all bonds were formed between electropositive and electronegative units. But this theory could not cope at all with the fact that the common atmospheric gases such as nitrogen and oxygen were diatomic and it was of little help in understanding the ever-growing number of organic compounds.

It is tempting to view nineteenth-century chemistry as the progressive articulation of atomic theory. To the laws of

definite and multiple proportions were added Avogadro's hypothesis that equal volumes of gases contain equal numbers of particles and Kekulé's discovery that organic compounds could be represented as chains or rings of tetravalent carbon atoms. It even became possible to assign definite geometric structures to molecules.

Yet there was on-going scientific and philosophical resistance to the atomistic research programme. Some of it was a result of general methodological caution. Chemists were still very aware of the phlogiston debacle which John Herschel described as ' a lamentable epoch in which…as if to prove the perversity of the human mind, of two possible roads, the wrong was chosen' (1830: 300). The so-called 'atomic debates' at the British Chemical Society in 1869 illustrate the concern of chemists to avoid a naïve belief in hypothetical entities that were admittedly useful but not directly tied to experiment.

Other objections stemmed from specific conceptual lacunae or flaws within the contemporary theory. For example, if one took seriously the rigid geometrical structure attributed to carbon, how could one account for the so-called 'Walden inversion' in which the molecule apparently turned wrong-side out? Why should atoms have discrete valences or combining powers in the first place, such that nitrogen hooked up with three hydrogens and oxygen combined with two, while chlorine was satisfied with only one? And how could the family relationships and trends among the elements, so nicely summarized in Mendeleev's periodic table, ever be explained in terms of periodicities or trends within the numerical values of atomic weights?

By the end of the century the most vigorous opponents of atomism, Ostwald, Mach and Duhem, could offer an alternative research programme, that of classical thermodynamics. This approach appeared to be much more closely tied to measurable quantities such as temperature and heats of reaction and its treatment of chemical processes required no assumptions about either mechanisms or the microstructure of the reactants. Mach and Duhem both had strong philosophical reasons for favouring phenomenological theories and Ostwald developed an entire metaphysical system based on 'energetics'.

Thermodynamics did indeed give valuable insights into reaction equilibria and the stability of chemical compounds, but it did not displace atomism. Instead, Boltzmann, Planck and others argued that it could be reduced to statistical mechanics, a theory of moving atomic particles (see Thermodynamics). And through experiments with X-ray diffraction and radioactivity it became possible to measure quite directly exactly how many such particles there were in a gas sample and the distances between them in a crystal lattice.

4 Chemistry with electrons

In the early twentieth century chemistry was revolutionized by the discovery that the atom has parts, and by 1932, when the neutron was discovered, the basic features of our present picture of the chemical atom were firmly in place. The defining characteristic of a chemical element now became the number of protons in the nucleus - atomic weights were no longer universal constants but mere averages of isotopic distribution in the earth's crust. Valence, a useful empirical concept that had previously been devoid of theoretical interpretation, could now be related to the configurations of the outer electrons surrounding the chemical nucleus.

Since there was little opposition to the new chemistry, explicit recognition of just how radically concepts had been changed was slow in coming. Not only were chemical atoms divisible (through ionization as well as through nuclear fission), but even more fundamentally there were now no units that remained invariant during chemical processes. The closest candidate perhaps would be the kernel of the chemical atom - the nucleus plus the filled inner electron shells - but then, paradoxically it is the electrons outside of the kernel that are essential to chemical bonds.

The new concept of chemical element also deviated considerably from the traditional one. Not only was the law of conservation of matter revised by relativity theory, nuclear reactions violated Lavoisier's law of the conservation of elements. In a sense Lavoisier's operational definition of element as the last product of analysis could still be relied on to reveal the simplest homogeneous 'stuffs' out of which everything was constructed, but the arché of the universe now turned out to have no resemblance to the elements of the chemist, but to be instead the fundamental particles of the physicist. Even if one could restrict the methods of analysis to so-called chemical ones in a non-question-begging way, it was now clearer than ever that the relationship between the properties of the simple substance (for example, elemental carbon) and the properties of the stuff which was conserved in chemical reactions (for example, the element carbon) were extremely complex.

Of particular interest to philosophical accounts of the development of science are the interactions between chemical theories of bonding and atomic physics during the first quarter of the century. To chemists the discovery of the electron immediately provided the key to an understanding of all sorts of electrochemical phenomena, and a theory of ionization could account for properties of solutions of weak and strong electrolytes. Bohr's theory of discrete electron orbits, each containing a maximum number of electrons, also seemed to account for some of the similarities and trends summarized by the periodic table. However, the Bohr model, which was designed to account for the spectra of isolated atoms, postulated moving electrons, and it was not at all clear how it could be extended to cover the distribution of electrons in compounds. Theoretical chemists struck out on their own and in 1916 G.N. Lewis attempted to give a unified account of ionic and covalent bonding, which was based on the idea of the special stability of electron pairs and octets. According to Lewis, bonding electrons were always arranged at the corners of a cube, atoms could complete their octets by sharing corners or faces of their cubes, and ionic bonds formed when the sharing was unequal.

Lewis' account made a certain amount of sense to chemists although it predicted an inaccurate geometry for carbon compounds. It also served to dramatize the inadequacies of what we now call the old quantum theory.

Although scientists can live for some time with inconsistencies within a theory, or contradictions between mutually relevant theories, the drive for consistency is an enduring one and it was a great triumph when in 1926 Schrödinger proposed a quantum mechanical account of the atom which appeared to be applicable to chemical bonds as well as atomic spectra. By conceptualizing electrons as three-dimensional charged clouds one might hope to show that they were denser in just those regions of space where chemists were accustomed to draw lines or pairs of dots to represent chemical bonds. However, actually carrying out the derivations was a formidable problem. When the physicists Heitler and London set out to calculate the bond energy of H_2, the simplest molecule of all, they were forced to adopt a simplified representation of the interactions between four charged bodies (two protons and two electrons) and as a result were able only to approximate the observed values.

If quantum mechanics was to be of any benefit at all to chemists, more rough and ready methods of modelling complex systems had to be found. And there sprang up two rival schools of quantum chemistry: Linus Pauling's valence bond approach seemed well-suited to describing the geometry of covalent molecules, while Robert Mulliken's molecular-orbital approach was particularly useful in describing the vibrational spectra of molecules. There is still debate about the relative merits of these two approaches and both continue to be presented in contemporary chemistry textbooks.

5 Current philosophical issues

What has most intrigued philosophers about twentieth-century chemical theory is the question of whether chemistry is reducible to physics. While it is obviously desirable that theoretical chemistry be *compatible* with quantum mechanics, the demand that it be *reducible* is a much more stringent and controversial goal, for reduction requires that the entire theoretical and empirical corpus of chemistry be derivable from, or reproducible within, the explanatory structure of physics.

The quest for reduction is a recurring scientific ideal, but it was particularly popular with the logical positivists who founded a unity of science movement (see Vienna Circle §4; Unity of science). The paradigm candidate for a successful reduction pair was classical and statistical thermodynamics, but it is also frequently claimed by both scientists and philosophers that it is no longer possible to do foundational theoretical work in chemistry because, after all, chemistry is really nothing more than the application of quantum mechanics to complicated arrays of electrons and nuclei.

While few would dispute the claim of reducibility in principle, there are many who find the project of analysing the actual relationships between the two disciplines to be a challenging and instructive one. Consider, for example, the puzzles surrounding the *aufbau* principle. It is often claimed that the striking chemical similarities among elements summarized by Mendeleev's periodic table can be given a straightforward explanation in terms of quantum mechanics. One simply 'builds up' the table by placing electrons in the lower energy levels first and demonstrates that elements in the same chemical group turn out to have similar electronic configurations. Thus, the outer electrons of fluorine ($2s^2p^5$) and chlorine ($3s^2p^5$) differ only in their principal quantum number. However, this simple procedure fails when one tries to build up the transition elements because the ordering of orbits by

energy levels is not invariant with nuclear charge. So, for example, in nickel (atomic number 28) the 4s level is filled before the 3d level while in copper (atomic number 29) the 3d level is filled at the expense of the 4s! This ’crossing over’ of energy levels can in theory be derived from first principles, but in practice, quantum chemists resort to *ad hoc* rules of thumb, referring to the increased stability of filled and half-filled sub-levels in order to summarize such deviations from the simple *aufbau* recipe.

Philosophers, theoretical chemists and chemistry educators continue to wrestle with the many puzzling conceptual features of contemporary chemistry. Given the holistic character of quantum mechanics, how can we justify chemical explanations which treat atoms and molecules as discrete entities? It has even been argued that quantum mechanics does not permit talk about the shape of a molecule! Can one defend or at least clarify the eclecticism of chemists who switch from valence-bond thinking to an molecular-orbital account according to convenience?

Current chemistry also serves as a strategic site for philosophers who wish to develop more detailed and realistic accounts of methodological issues which arise in many sciences: how to deal with mathematically intractable representations, the role and evaluation of approximate explanations, the analysis of experimentation and instrumentation. Because of its central role in military, industrial and environmental affairs, chemical research has also come under the scrutiny of philosophers interested in the ethical and social dimensions of science (see Responsibilities of scientists and intellectuals).

Cheng

In early Confucian writings, cheng *describes the quality of authentically realizing or 'completing' a given thing's true nature. It appears together with* xin *(trustworthiness), a character to which it is related in sense.* Cheng *refers primarily to the fulfilment of a thing's true nature, while* xin *refers to the quality resulting from this. With regard to human beings, cheng is the authentic realization of ones nature. In texts such as the* Xunzi *and* Zhongyong*, the idea is related to the role human beings are believed to play in realizing or 'completing' a greater universal pattern. This development becomes centrally important for later neo-Confucian thinkers, who see these as different aspects of a single project.*

Cheng ('integrity' or 'sincerity') is not a central term of art for Confucius, but it takes on greater significance in the thought of Mencius and Xunzi. According to the *Mengzi* (4A12), *cheng* requires an understanding of the good. One cannot be *cheng* unless one understands why one is acting as one does. To be *cheng* is to be true to one's self, that is, one's true nature (hence 'sincerity'). Thus *cheng* is necessary for the cultivation of genuine virtue. Since such self-cultivation results in the most satisfying of lives (see Self-cultivation, Chinese theories of), there is no greater joy than to find that one is *cheng*.

For Xunzi, *cheng* assumes greater prominence: 'Nothing is more beneficial for nourishing one's heart-mind', and 'the extension' of this excellence is the beginning and end of the moral life (*Xunzi* 3). Xunzi introduces the idea that one who is *cheng* has the power to transform both people and things. One who is *cheng* and *xin* (trustworthy) is 'like a spirit'.

All the above ideas are further developed in the Daxue (Great Learning) and Zhongyong (Doctrine of the Mean). The former emphasizes that *cheng* is primarily concerned with one's internal mental states by calling for all to *cheng* (make sincere) their *yi* (thoughts). One is to fulfil but not overstep the proper measure in one's perception of and response to things and events. In the *Zhongyong* we find the most complete development of the notion of *cheng*. Echoing Xunzi, the text gives *cheng* a strongly metaphysical sense: it is each thing's realization of its proper nature as part of a grand cosmic pattern. Bringing this state of affairs about is the highest purpose of human life. Thus, '*cheng* is the way of heaven and to realize *cheng* is the way of human beings'. One is to realize *cheng* by fulfilling (that is, completing) one's own nature. This in turn allows one to complete the nature of others and go on to complete the nature of all things, thus 'forming a triad with heaven and earth'.

The notion of *cheng* was extremely important for neo-Confucian thinkers. Cheng Yi offered what became the standard interpretation. Discussing 'nature' and *cheng*, he explained that the former was a substantial thing while the latter was the quality of that thing's being fully realized as it should be: 'If you compare the nature to this fan, integrity (*cheng*) may be compared to this fan being properly made' (Graham 1992: 67).

Graham, A.C. (1992) *Two Chinese Philosophers*, La Salle, IL: Open Court.(An insightful study of two neo-Confucian thinkers, Cheng Hao and Cheng Yi; contains helpful discussions of *cheng*, particularly on pages 67-73.)

Cheng Hao (1032-85)

*Cheng Hao was a pivotal figure in the creation of a Confucian tradition that was to become the basis for intellectual and state orthodoxy in China from the thirteenth century to the twentieth century. His decision to seek the Confucian Way (*dao*) through a direct and personalized reading of the classics was later projected as the beginning of this movement. From a new perspective, he redirected Confucian discourse on such cardinal concepts as humaneness and human nature.*

Born into a family which for three generations had distinguished itself in high offices, Cheng Hao accompanied his father to a succession of posts in central China. At the age of twenty he passed the national civil service examination and, for most of the years until 1180, had a notable official career which culminated in 1169-70 with service at the emperor's court. During audiences with the emperor and in written memorials, he followed the example of Mencius in admonishing his ruler to follow benevolence and refusing even to discuss what would bring profit and advantages. So critical was he of Wang Anshi's utilitarian obsession with maximizing advantages and the happiness of the greatest number of people that Cheng was demoted to a local post and eventually dismissed entirely. The last five years of his life he devoted to teaching an increasing number of disciples, drawn in part by his exceptionally gracious and warm disposition.

Retrospective biographical accounts focused on his youthful fascination with Daoism and Buddhism, until his resolve to discover the Way (*dao*) led him to the classics (see Chinese Classics). Reading the classics in the context of his commitment to the Way, he was credited with a breakthrough in understanding the mind and heart of Mencius and reviving the transmission of the Way that had been lost since this last sage of the classical era.

Cheng Hao was the first to expound the idea of 'principle' (*li*), the normative patterns providing coherence to all things, as a Confucian concept, but his younger brother Cheng Yi was the one who developed it into a Confucian philosophy (see Li). By equating human nature (see Xing) with principle and the Way, neither brother regarded human nature as merely the raw human state. Although the younger brother would refer to human nature, principle and the Way as good, Cheng Hao considered them beyond any opposite, so he did not describe them as good. The opposite of good arose, like dysfunctional behaviour, from imbalance and deviation from the Mean. Cheng Hao also first broadened the Confucian idea of humaneness (*ren*) to encompass not only a profound sympathy with all beings but also a mystical oneness with the universe. Drawing support from a medical text, he noted that paralysis of the human limbs was described as an absence of *ren*; thus, it was the life force running through things. Seeking to teach spiritual cultivation of the self in order to realize the unity with all things, he condemned ego-centredness as a barrier to achieving this sense of oneness (see Confucian philosophy, Chinese §5; Neo-Confucian philosophy §5).

Cheng has been interpreted primarily in two ways. Beginning with Zhu Xi's synthesis of the Confucian Way tradition (see Zhu Xi), Cheng and his younger brother have been presented as a unified voice and as students of Zhou Dunyi. This formulation facilitated Zhu's synthesis of diverse ideas, but even some of his contemporaries questioned his historical and philosophical accuracy. Other scholars, most notably Fung Yu-lan (1953), put Cheng Hao at the head of a subjective wing of Confucianism and his younger brother at the beginning of a rationalistic wing that culminated in Zhu Xi. Both conventional views have, since the 1980s, come to be regarded as exaggerated.

Cheng Yi (1033-1107)

One of the most creative Chinese intellectuals, Cheng Yi was the most systematic and influential of a group of thinkers which channelled Confucian thinking into a new philosophical direction that gradually became dominant in East Asia for several centuries. Buddhism was still the most pervasive and sophisticated religious philosophy of his day; yet he effectively borrowed some of its ideas and methods to formulate a philosophy that would enable Confucian teachers to draw intellectuals away from the Buddhist masters.

Born to a scholar-official family, Cheng Yi lived most of his life around Luoyang, traditionally the secondary capital of China. Although he passed the major part of the highest civil service examination in 1059, he failed the culminating palace examination. Thereafter he lost interest in an official career and devoted himself to learning and teaching the 'Way' (*dao*) of the sages. Though he attracted a few early students, his prominence as a Confucian master came in his mid-fifties when he was appointed a lecturer to the emperor and subsequently a professor in the national academy. Even though his official career was thus limited to educational posts held late in life, his outspoken ideas and uncompromising demeanour eventually provoked the government to confiscate his land and exile him for three years. When he died in 1107, only the most loyal of his students dared to attend his funeral.

His followers developed a fellowship of Confucian intellectuals through which his ideas were disseminated. When in the twelfth century Zhu Xi systematized philosophical reorientations of Confucian traditions for what soon became mainstream thinking and subsequently state orthodoxy, he drew more heavily on the ideas of Cheng Yi than any other eleventh-century master.

The central concept in Cheng Yi's philosophy was 'principle' (*li*), the normative patterns inherent in and providing coherence to each and every individual thing (see Li). While his elder brother Cheng Hao used 'principle' to point to a moral force alive in all things, Cheng Yi postulated it as the metaphysical basis of the harmony of the one and the many. Seeking to refute the Buddhist doctrine of 'emptiness' (*śūnyatā*) (see Buddhist concept of emptiness). Cheng Yi pointed to the linkage between the philosophical, ethical ultimate and the myriad things in daily life in order to fortify Confucian belief in the significance of structures, words and deeds in the sociopolitical realm. For instance, identifying human nature with principle provided a more philosophical basis for Mencius' doctrine of the goodness of human nature (see Mencius; Xing). Moreover, as a way of explaining the existence of dysfunctional behaviour, Cheng Hao pointed to the interaction between principal and the psychological energy (*qi*) that constitutes the 'stuff' of all people and things (see Qi). Ironically, as Yü Ying-shih (1987) shows, Cheng Yi developed Confucian 'this worldly' ethics after gaining insights into Chan disciplinary methods of meditation and spiritual cultivation. Perhaps because of the nature of his borrowings from Buddhism, his most frequent criticism of Buddhists was not their metaphysics, but their alleged selfishness in devaluing relations in family and society.

The concept of principle also provided a more sophisticated paradigm than the correlative cosmology developed over a thousand years earlier for explaining what was known about the natural world. Like that earlier synthesis, however, Cheng Yi was using the science of his day to bolster traditional values and roles associated with Confucian ethics. For instance, he rejected earlier Confucians' equating the cardinal virtue of humaneness (*ren*) with altruistic love (see Confucian philosophy, Chinese §5). Love was just a secondary attribute, because humaneness as principle denoted the oneness of all beings.

In Peter Bol's analysis, Cheng Yi made a radical break with the approach that the literati elite took to learning (Bol 1992). Whereas several centuries of intellectuals had focused on literary culture as the medium for understanding culture and values, Cheng announced that the mind could directly grasp the moral patterns inherent in the natural world. Thus, instead of responding primarily to the Buddhist challenge, Cheng was essentially intent on winning the sociopolitical elite to his view of the grounds of ethical values.

Graham, A.C. (1986) 'What Was New in the Ch'eng-Chu Theory of Human Nature?', in Chan Wing-tsit (ed.) *Chu Hsi and Neo-Confucianism*, Honolulu, HI: University of Hawaii Press. (Perhaps the best study in English of Cheng Yi's view of the central Confucian problem of human nature.)

Tillman, H.C. (1992) *Confucian Discourse and Chu Hsi's Ascendancy*, Honolulu, HI: University of Hawaii Press. (A study of the Confucian fellowship and its ideas beginning with Cheng Yi and continuing through its establishment as orthodoxy in 1241.)

Yu Yingshi [Yü Ying-shih] (1987) *Zhongguo jinshi congjiao lunli yu shangren jingshen (The Religious Ethic and Mercantile Spirit in Modern China)*, Taibei: Lianjing. (Refutes Max Weber's findings about Chinese religion, but uses the question poised by Weber about the impact of religious values on merchant class values to explore changes in Buddhism and Confucianism, beginning respectively in the Tang and Song periods. An expanded English version is forthcoming.)

Chernyshevskii, Nikolai Gavrilovich (1828-89)

Nikolai Chernyshevskii was the main theorist of the Russian democratic radicalism of 'the 1860s' or, more precisely, of the period of political 'thaw' and liberal reforms which followed Russian defeat in the Crimean War and the enthronement (in 1855) of Alexander II. He was also the best representative of the non-conformist elements among the raznochintsy*, that is, the educated commoners, who at that time began to figure prominently in Russian intellectual and social life. As such, he exerted a powerful formative influence on the Russian intelligentsia.*

In 1862 Chernyshevskii was arrested, brought to trial and, despite insufficient evidence, condemned to lifetime banishment in Siberia. In exile, preserving his integrity to the end, he stoutly refused to ask for clemency (as a result, he remained in a remote Siberian village until 1883). In prison, waiting for trial, he wrote the novel Chto Delat' (What Is To Be Done?) in which he showed the 'new men' of Russia - 'rational egoists', devoted to the cause of progress, and even a type of ascetic, self-sacrificing revolutionist. Thanks to a strange oversight of the censor the novel was serialized in the journal Sovremennik (The Contemporary) and, despite lack of literary distinction, became a powerful source of inspiration for several generations of Russian progressive youth.

Chernyshevskii's philosophical reputation was created by the Russian Marxists. The 'father of Russian Marxism', G.V. Plekhanov, greatly impressed by Chernyshevskii's combination of Feuerbachian materialism and respect for Hegelian dialectics, described him as an important precursor of dialectical materialism. This view was taken up by Lenin who in Materialism and Empiriocriticism called Chernyshevskii 'the great Russian Hegelian and materialist', the only Russian philosopher before Marxism who was able to defend 'integral materialism' against the agnosticism and subjectivism of Neo-Kantians, positivists, Machists and 'other muddleheads'. Soviet philosophers went even further: Chernyshevskii was treated by them not only as the greatest Russian philosopher before Marxism, but also as the greatest pre-Marxian philosopher of the world, founder of the highest form of pre-Marxian materialism. For several decades this was the obligatory dogma of the Soviet official ideology.

After the breakdown of the Soviet Union, interest in Chernyshevskii's philosophy almost completely disappeared in Russia. It is impossible, however, to deny Chernyshevskii's importance in Russian intellectual history. Hence the need of rethinking his philosophical legacy.

1 Aesthetics

Nikolai Gavrilovich Chernyshevskii, son of an Orthodox priest in the city of Saratov, intended initially to become a priest himself. However, he changed his mind and, after graduating from a theological seminary, entered the faculty of history and philology at St Petersburg University. During his studies in St Petersburg he became acquainted with the works of Hegel and Feuerbach, as well as with the writings of the French utopian socialists. His favourite Russian thinker was the literary critic V.G. Belinskii. Young Chernyshevskii fully shared Belinskii's view on the special mission of literature and literary criticism in autocratic Russia. He decided, therefore, to provide literary critics with a theoretical clarification of the essence of art (with particular emphasis on literature) and of the role of art in society. He fulfilled this task in his master's dissertation 'Ėsteticheskie otnosheniia iskusstva k deistvitelnosti' (The Aesthetic Relations Between Art and Reality) (published and publicly defended in the spring of 1855).

Chernyshevskii's dissertation (as he himself explained in the preface to its third edition, 1888) was in fact a critique of Hegelian aesthetics from the point of view of Feuerbachian materialism. However, the Draconian censorship regulations, introduced in 1848 and still holding at the time of its writing, made it impossible to refer openly to Hegel and Feuerbach. Hence, Chernyshevskii's thesis took the form of a sharp critique of the Hegelian aesthetics of F.T. Visher, seen as a representative specimen of the 'dominant aesthetic theory'.

Against Hegelian idealism, defining beauty as a manifestation of the Absolute Idea, Chernyshevskii set his own conception, which reads as follows: 'Beauty is life; beautiful is that being in which we see life as it should be according to our conceptions'. In accordance with Feuerbach's anthropological materialism, this was to be a materialist and an anthropocentric conception: materialist, because 'life' was seen in it as rooted in nature and the beauty of art was interpreted a mere reflection of natural beauty; anthropocentric because the human being in the

full flowering of his faculties was made the measure of all things and the supreme ideal of beauty. Chernyshevskii conceded that this anthropological ideal could be interpreted in different ways, depending on historical and social circumstances, but strongly insisted that the aesthetic ideas of the privileged classes reflected an artificial life and were, therefore, normatively illegitimate. Only the working people, living in touch with nature, were the true representatives of the human species and thus the living embodiments of the supreme aesthetic ideal. In this way the Feuerbachian 'rehabilitation of nature' was linked with a cult of the common people and with the demand for the widest possible democratization of art.

Chernyshevskii's programmatic naturalism led to the conclusion that art was merely a surrogate for reality. Against aesthetic idealism Chernyshevskii set the view that works of art could only copy real life and that artists, therefore, could not claim to possess genuinely creative power. Nevertheless, he also stressed, somewhat inconsistently, that the function of art is not only to reproduce reality, but also to explain and evaluate it - to 'pass judgment' on the real-life phenomena that have been recreated in it. He made it explicit that because of this art, especially literature, could and should perform a socially useful didactic role, and that artists, especially writers, could and should become spiritual leaders of society.

Chernyshevskii's aesthetic ideas aroused very different reactions. Critics who defended uncommitted 'pure art' were horrified by them; Ivan Turgenev, expressing the views of many liberal-minded writers, reduced them to 'blind malice and stupidity'; in contrast with this Dmitrii Pisarev praised Chernyshevskii's thesis as a total elimination of aesthetics in the name of utilitarian values. On the whole, the acceptance or non-acceptance of the 'Aesthetic Relations Between Art and Reality' marked the difference between Russian liberals and democratic radicals. The latter enthusiastically embraced Chernyshevskii's ideas, treating them as obligatory guidelines for progressive literary criticism.

Soviet literary scholars used to emphasize that in *What Is To Be Done?* Chernyshevskii did not limit himself to a critical explanation and evaluation of the existing reality but also expounded positive ideals - an image of a revolutionary hero and a vision of a socialist society of the future. This allowed them to treat Chernyshevskii as an important precursor of 'socialist realism'.

2 The anthropological principle

Chernyshevskii's philosophical position was best defined in his 'Antropologicheskii printsip v filosofii' (Anthropological Principle in Philosophy) (1860), a work written in connection with Lavrov's *Sketches* (see Lavrov, P.L. §1). (Contrary to most commentaries, Chernyshevskii endorsed Lavrov's anthropologism and only wanted to remove from it what he saw as concessions to idealism and eclecticism).

For Chernyshevskii the 'anthropological principle' supplied the theoretical foundation for the integral wholeness of man, the abolition of the eternal dualism of body and soul. The human individual, he argued, has only one indivisible nature and only as such can he represent an absolute value to other human beings. In Chernyshevskii's interpretation this principle was a cornerstone of an entire philosophical worldview (see Russian Materialism: 'the 1860s').

First, it was conceived as the reinstatement of a distinctively Feuerbachian, anthropocentric materialism, that is to say, a form of materialism capable of resisting all forms of idealism without becoming fully dependent on the dehumanized, mechanistic world of the natural sciences. Chernyshevskii intended his materialism to provide a basis for value-judgments; hence he had to distance himself from the cold abstractions of value-neutral objectivist scientism.

Second, Chernyshevskii's materialism was a theory of the human organism as both knower and object of knowledge - thus positing the indivisibility of matter and consciousness. For man, Chernyshevskii reasoned, the primary datum is not thinking but existence, including bodily existence in the material environment. He saw this standpoint as undermining the foundation of idealistic epistemology and proving decisive arguments against subjectivism and agnosticism.

Finally, the anthropological principle was conceived as a philosophical underpinning of the ethical conception of 'rational egoism' - a conception based on the premise that, ultimately, the guiding principle of conduct is individual interest. In the normative sphere this theory gave preference to utilitarianism, rationalism and

egalitarianism. It postulated that the standard by which human actions must be judged is the benefit they bring - that good is not an autonomous value but only a lasting benefit, ‘a very beneficial benefit’. The rational egoist accepts other people’s right to be egoists because he knows that all people are equal; in controversial issues he is guided by the principle of the greatest good of the greatest number. In interpreting this utilitarian principle Chernyshevskii differed from Bentham’s belief in the self-regulating market; he followed instead Feuerbach’s view that truly rational individuals were communal beings, capable of conscious cooperation in pursuing mutually agreed common ends. His social ideal was therefore a cooperative socialism, presupposing the full liberation of the individual from all sorts of blind faith and authoritarian compulsion. He outlined this vision in *What Is To Be Done?*, emphasizing in particular the full emancipation of women.

3 Political philosophy

Chernyshevskii’s political philosophy concentrated on problems relevant to Russia as an underdeveloped country, a ‘latecomer to the arena of history’.

In many points - in his commitment to the idea of the liberation of the individual, in his conviction that Russia should still learn from the West and humbly recognize the superiority of Western achievements - Chernyshevskii continued the line of Russian Westernism. In the essay ‘O prichinakh padeniia Rima’ (What Caused the Downfall of Rome?) (1861) he criticized all Russian conceptions of the ‘senility’ of the West, including Herzen’s ‘Russian socialism’ (see Herzen, A.I.). And yet there was a time (1856-7) when he thought it appropriate to cut himself off from the epigones of Westernism and to declare that in many respects he stood closer to the Slavophiles. He even proposed to the Slavophiles a kind of alliance for the joint defence of the peasant commune against the liberal economists, who demanded that it be abolished together with feudal bondage. This alliance, however, could not be concluded because the differences between the two partners were too important: the Slavophiles wanted to preserve pre-capitalist social relations, while Chernyshevskii saw the commune as a suitable means for a direct transition to a rational socialist collectivism.

In his articles on political economy (which were criticized but highly appreciated by Marx) Chernyshevskii set against bourgeois liberalism a conception of ‘the political economy of the working people’. He fully recognized the progressiveness of capitalist development in the West, but was aware of its contradictions and wanted for his country a more humane and, at the same time, a more rapid type of progress. In his ‘Kritika filosofskikh predubezhdenii protiv obshchinnogo zemlevladeniia’ (Criticism of Philosophical Prejudices Against the Peasant Commune) (1859) he argued that Russia, and backward countries in general, could benefit from the experience and scientific achievements of the West and ‘skip the intermediate stages of development or at least enormously reduce their length’. His main argument for the commune was based on a dialectical conception of progress: the first stage of any development is, as a rule, similar in form to the third; thus primitive communal collectivism is similar in form to the developed collectivism of a socialist society and can make easier a direct transition to it.

Chernyshevskii’s criticism of the liberals was also levelled against political liberalism. He published in his journal *Sovremennik* a series of articles on the revolutions in France in which he sharply distinguished between liberals, who aimed at ‘merely political’ freedom, and democrats, whose main concern was the social welfare of the people. He did not hesitate to say that from the democratic point of view Siberia was a better country than England because Siberian peasants were better off than English proletarians (‘Iulskaiia monarkhiia’ (The July Monarchy) 1858). This populist conception of democracy exerted a mighty influence on the Russian revolutionary movement. Members of the revolutionary organization Land and Freedom treated Chernyshevskii as their intellectual leader and often asked him for advice.

However, Chernyshevskii himself did not embrace revolutionary solutions. Undemocratic methods used to prepare the abolition of serfdom in Russia, as well as his own unlawful arrest and trial, convinced him that the main obstacle on the way to true progress in Russia was lack of the rule of law and political freedom. Therefore in his ‘Pis’ma bez adresa’ (Letters Without Addressee) (1862) - whose addressee was actually Alexander II - he sided with the gentry liberals of Tver’, who demanded a liberal constitution for Russia. In the penal settlement in Siberia he surprised his fellow prisoners by a total reversal of his previous view of political freedom. It is true, he argued, that political freedom cannot feed a hungry man, but without food people can survive several days, while without air they cannot live more than a few minutes. As air is necessary for the life of the human organism, so political freedom is necessary for the normal functioning of society.

Nevertheless, Russian liberals did not claim Chernyshevskii's legacy, thus allowing the revolutionists to take a monopolistic hold on it and to interpret it accordingly. The reception of Chernyshevskii's political ideas was therefore extremely one-sided. He was seen as an intransigent enemy of liberalism, preaching class struggle, categorically rejecting all half-way reforms and pushing Russia onto the path of agrarian revolution. This interpretation was radicalized by Lenin, in whose eyes Chernyshevskii was the greatest, most consistent representative of pre-Marxian 'revolutionary democracy' in Russia. The Soviet Marxists accepted this view and tried to present 'revolutionary democratism' as the most advanced political position before the emergence of Marxism.

Chillingworth, William (1602-44)

Chillingworth was one of the most notable English-speaking contributors to debates between Protestants and Catholics in the seventeenth century. His use of a distinction between metaphysical and moral certainty proved extremely influential, as did his rationalist and fallibilist approach to issues of faith and authority.

William Chillingworth was born in England at Oxford, and was educated there at Trinity College, where he became a fellow in 1628. In the same year he renounced his allegiance to the Church of England, resigned his fellowship and became a Roman Catholic. He travelled abroad to a Catholic seminary in the Netherlands, probably at Douai, possibly at St Omer, but soon found the life uncongenial and returned to England. In the early 1630s he had no clear religious allegiance, but was reconciled to the Church of England by 1635. From 1634 he lived at Viscount Falkland's house at Great Tew in Oxfordshire; Falkland's posthumously published *Discourse of Infallibility* (1645) owes much to Chillingworth's arguments. In the autumn of 1637 Chillingworth published his chief work, *The Religion of Protestants a Safe Way to Salvation*, directed against the Jesuit Edward Knott. When the Civil War broke out he sided with the King, and died as a prisoner of war in January 1644, following his capture at Arundel.

As its title indicates, *The Religion of Protestants* is a work of religious controversy, not a philosophical treatise. In this respect it resembles Hooker's *Laws of Ecclesiastical Polity* (1593-1600), but whereas Hooker adopted a strategy of laying down general principles and thereby out-flanking his opponents, Chillingworth chose to fight on his opponent's ground (see Hooker, R.). The structure of the work is therefore dictated entirely by its target, Knott's *Mercy and Truth. Or Charity Maintained by Catholickes* (1634). This choice of tactics reflected the fundamental characteristics of Chillingworth's mind, essentially critical and combative rather than speculative or constructive. At Oxford he had acquired a near-legendary reputation for agility in debate, and he was understandably confident of his capacity to subdue any opponent.

Knott and Chillingworth both unequivocally accepted the infallibility of the Bible, but differed as to whether this was enough. For Knott, infallible Scriptures need to be expounded by an infallible interpreter; otherwise nothing could ever be certain in religion, and faith would degenerate into mere opinion. Chillingworth adamantly denied this. The Scriptures provide an infallible rule by which controversies are to be judged, but no infallible judge of their meaning exists on earth, either in the person of the Pope or anywhere else. No church has therefore the right to claim infallibility for its articles of faith. The Church of England claims no more than 'an Authority of determining Controversies of Faith, according to plain and evident Scripture and Universal Tradition' (Chillingworth 1638: ii.162); neither its articles nor those of the Lutherans or the Calvinists possess the infallibility of the Scriptures from which they are derived. It is this that lies behind Chillingworth's most often quoted dictum - so misleading when taken out of context - that 'The BIBLE, I say, the BIBLE only, is the Religion of Protestants!' (Chillingworth 1638: vi.56).

Chillingworth saw Knott's position as resting on two fundamental confusions - that of infallibility with authority, and of infallibility with certainty. Not all certainties are the same - indeed two quite separate kinds need to be distinguished. Metaphysical certainty belongs to direct revelations from God, to self-evident propositions and their logical consequences, and to the direct testimony of the senses. Faith cannot have this kind of certainty - if it could it would no longer be faith, but knowledge; it can, however, be morally certain - that is, probable to the highest degree. This is the only certainty that historical propositions can ever possess. Chillingworth naturally rejected Knott's scriptural and patristic arguments for papal infallibility, but he also insisted repeatedly that, even if successful, they could give the doctrine moral certainty only, not the infallible, metaphysical certainty that Knott's position required.

Chillingworth's approach to theology was unswervingly rationalist: 'neither God doth nor man may, require of us as our dutie, to give a greater assent to the conclusion, than the premises deserve' (Chillingworth 1638: ii.154). Blind faith is in no way meritorious: 'God hath given us our Reason to discern between Truth and Falshood, and he that makes not this use of it, but beleeves things he knowes not why, I say it is by chance that he believes the Truth, and not by choice: and that I cannot but feare, that God will not accept of this *Sacrifice of fooles*' (ii.113). It is hardly surprising that this did not find favour with Chillingworth's opponents, either Catholic or Protestant.

Their doubts about the reality of Chillingworth's own faith were quite unfounded, as his sermons made plain, but suspicions that he might not be the safest of allies were more understandable. As Hobbes, who had met him at Great Tew, sardonically observed, 'he was like a lusty fighting fellow that did drive his enemies before him, but would often give his owne party smart back-blowes' (Aubrey 1898 vol. 1: 173).

Locke greatly admired Chillingworth, and the two men had much in common (see Locke, J. §7). Both were accused by hostile critics of Socinianism, wrongly in Chillingworth's case (see Socinianism), and both can more fairly be regarded as credal minimalists: 'wee suppose that all the necessary points of Religion are plaine and easie, & consequently every man in this cause to be a competent Iudge for himself' (Chillingworth 1638: ii.16). They shared a deep loathing of religious persecution, not merely for its cruelty, but for its presumption: 'God hath authoriz'd no man to force all men to *Unity of Opinion*' (Chillingworth 1638: ii.85).

A few months before *The Religion of Protestants* appeared, Descartes' *Discourse on Method* was published in Holland. Chillingworth had no knowledge of Descartes' work and their two projects were utterly dissimilar; the fundamental congruence of their epistemology is therefore all the more striking (see Descartes, R. §3). Both take as basic the cognitive sovereignty of the individual. Authority may be accepted, but has first to be judged by reason, and this is something that each one of us has to do alone.

Chinese Classics

The Chinese Classics are a group of texts of divination, history, philosophy, poetry, ritual and lexicography that have, to a significant extent, defined the orthodox Ruhist (Confucian) tradition of China. Since the Song dynasty (960-1279), they have consisted of the following thirteen texts:

(1) The Shujing, or Shangshu (Book of Documents, or Documents), the 'classic' of Chinese political philosophy. Allegedly compiled by Confucius, it contains a variety of historical documents, mostly dating from the fourth century BC.
*(2) The Yijing (Book of Changes), a divinatory work using sixty-four permutations of broken (*yin*) and straight (*yang*) lines in six positions. It has two parts: the 'Zhouyi' (Zhou Changes), an ancient divination manual, and the Shiyi (Ten Wings), a commentary dating from the Warring States period (403-222 BC).*
(3) The Shijing (Book of Songs, or Odes), a collection of 305 poems, ostensibly selected by Confucius, on a wide variety of subjects. It includes songs of farming, feasting and love that are clearly of popular origin. It also contains a variety of court poetry including dynastic hymns, hunting and banquet songs and political satires from the Zhou court (1121-222 BC).
(4) The Yili (Ceremony and Rites), a Warring States ritual text.
(5) The Zhouli (Rites of Zhou), another Warring States ritual text.
(6) the Liji (Book of Rites), a Han work that provides information about early Confucian philosophy and ritual. Together, works (4), (5) and (6) make up the Lijing (Classic of Rites).
(7) The Zuozhuan (Zuo Annals).
(8) The Guliangzhuan (Guliang Annals).
(9) The Gongyangzhuan (Gongyang Annals). Works (7), (8) and (9) are commentaries to the Chunqiu (Spring and Autumn Annals, or simply Annals), a chronicle of the reigns of twelve rulers of the state of Lu; its presentation of diplomatic and political events from 722-481 BC is terse and factual, but the three commentaries provide substantial elaboration and exegesis.
(10) The Analects of Confucius (Lunyu), containing anecdotes and short dialogues between Confucius and his disciples. In this work, Confucius established a new emphasis on humanistic ethics and political and social order.
(11) The Xiaojing (Book of Filial Piety), a short dialogue between Confucius and one of his disciples, concerned with filiality in both private and public life; it discusses children's filiality to their parents and subjects' filiality toward their rulers.
(12) The Erya, a book of glosses of Zhou dynasty terms (the title means 'Graceful and Refined').
(13) The Mengzi, which records a series of dialogues and debates between the philosopher Mencius and his students, several rulers and a variety of rhetorical and philosophical opponents. Mencius elaborated upon the Analects, arguing that human nature was inherently good and claiming that four 'sprouts' of goodness could be educated to create intuitive ability as the correct basis for moral judgments.

*The practice of appealing to authoritative texts appeared as early as the Analects of Confucius, around 500 BC. An explicit classical canon first appeared some four hundred years later during the Han dynasty (206 BC-AD 220), when Emperor Wu institutionalized a set of five classics associated with Confucius. At the same time he established new procedures for recruiting officials, created official chairs for the study of the Five Classics, restricted official academic appointments to those five areas and founded an imperial academy for the study and transmission of those works. In this way he effectively created a new 'Confucian' state religion. The term 'classic' (*jing*) also appears as the first of six categories of literature in the classification system of the bibliographical chapter of the Hanshu (History of the Former Han Dynasty). Classics (*jing*) are distinguished from masters (*zi*), the latter being grouped into nine schools starting with the Ru, or Confucians.*

Since the Han dynasty, the content of the classical canon has grown from the original five (or seven) texts, as established during the Han dynasty. The original group of classical texts that acquired official sanction during the early Han empire was supplemented by additional texts during the Tang (617-907) and Song (960-1279) periods. The Chunqiu (Spring and Autumn Annals) became known under the titles of three commentary editions, the Gongyangzhuan, Guliangzhuan and Zuozhuan, as noted above. The Lijing became known as three separate works on ritual, the Yili, the Zhouli and the Liji, again as noted above. The Erya was added to the classical canon during

the Tang dynasty and the Mengzi during the Song dynasty, bringing the total to what became the standard thirteen texts.

These works functioned as classics in a number of ways. They formed the core education of the bureaucratic elite, they provided an important source for imperial authority and they set the philosophical agenda for the dominant Confucian tradition. The classics are also significant for what they do not contain. Many of what are now considered the greatest philosophical works of the Warring States period are classified as masters, not classics; examples include the Zhuangzi, the Xunzi and (until the Song dynasty) even the Mengzi.

1 Early ideas of textual authority

The practice of citing textual authority can be traced to the Zhou dynasty (1121-222 BC). There is evidence that the practice of poetic quotation of selected portions from the *Shijing (Book of Songs)* was highly valued by the Zhou elite. Quotation from the *Shijing* (and, to a lesser extent, the *Shujing (Book of Documents)*) could be used to lend the authority of tradition to particular utterances. The ambiguity of quotation could also be used in a variety of diplomatic, domestic and political contexts to diffuse tension or criticize a hierarchical superior. In this sense, the origins of the classics involve the notion of criticizing authority. In the *Analects* of Confucius, three texts are commonly appealed to as sources of authoritative utterance: the *Shijing*, the *Shujing* and the *Yijing (Book of Changes)*. While the *Analects* thus contains a distinct notion of authoritative texts, there is no reference to an explicit classical canon of any kind.

Four works mark the beginning of what was later to become the Chinese classical tradition: the *Shujing*, the *Yijing*, the *Chunqiu (Spring and Autumn Annals)* and the *Shijing*. While tradition ascribes the compilation of these works to Confucius, they in fact date from the Zhou court between the ninth and sixth centuries BC. These annals and collections of poetry and ritual reflect the values and concerns of the Zhou aristocracy: sacrifice and warfare. The *Shujing* contains terse accounts of investitures, royal decisions and pronouncements and ritual dances, one of which, for example, celebrates the accession of King Wen of Zhou over the preceding Shang dynasty. The *Shijing* also contains sacrificial and ritual hymns from the Zhou court, as well as a variety of other popular songs. The *Chunqiu* is a series of ritual documents in careful chronological order. These may have originated as an historical archive of fire divinations, performed by heating pieces of tortoise shell or animal bone on which a divinatory inquiry had been inscribed. A second form of divination entailed the manipulation of yarrow stalks, where even and odd numbers corresponded to broken or unbroken lines that represented yin and yang respectively, in a complex scheme of sixty-four permutations. Of the various yarrow-stalk divination systems (*yi*) used in various contexts, only the Zhou system has been preserved; the *Zhouyi (Zhou Changes)* forms the core of the *Yijing* (see Yijing).

2 Definition of the canon

Mention of a canon of six classics first appears in the *Zhuangzi*, itself a particularly non-canonical text (see Zhuangzi). Chapter 14 of this work refers to six classics: *Shijing*, *Shujing*, *Lijing (Book of Rites)*, *Yuejing (Book of Music)*, *Yijing* and the *Chunqiu*. (A separate reference in the previous chapter mentions, but does not name, twelve classics.) The late Warring States philosopher Xunzi also refers to the same six, which he helped establish as canonical works of early Ruhist (Confucian) schools. The First Emperor of the Qin proscribed five of the six in 213 BC; the exception was the *Yijing*, presumably for its divinatory content. This imperial proscription, combined with the destruction of the Imperial Library in 207 BC, caused a serious breach in the transmission of these works, and the *Yuejing* may have been lost during this period.

The category of classics (*jing*) first appeared during the Han dynasty as an effort to create or re-create a textual canon. In 136 BC, under the influence of the philosopher Dong Zhongshu, the Emperor Wu of the Han promulgated a set of five classics associated with Confucius. He established five academic chairs for the specific study of five works, the *Yijing*, *Shijing*, *Shujing*, *Lijing* and *Chunqiu*. He further restricted the appointment of academicians to the specific study of those five classics. In 124 BC, also under the influence of Dong Zhongshu, he founded the Taixue, an imperial academy for the training and examination of students in those works, as a way of recruiting able officials. Students completing work at the academy were examined on the Five Classics in a written examination marking the beginning of the state examination system. These measures also established an explicit concept of a canon of classical texts in China, the importance of which cannot be underestimated. They raised Han

Confucianism to the status of a state religion, and established these works as the basis for the education of officials. Despite this official recognition of both texts and institutions, however, the Han dynasty saw considerable debate about the legitimacy of both texts and editions of texts. While the Five Classics was the most frequent articulation of the Han Confucian canon, a set of seven classics added the *Analects* of Confucius and the *Xiaojing (Book of Filial Piety)* to the original five.

Also during the Han period a classification system of six classes of literature emerged, of which the category of the classics was first and foremost. The bibliographical chapter of the *Hanshu (History of the Former Han Dynasty)*, edited by Ban Gu (AD 32-92) and based on an earlier compilation by Liu Xin (d. AD 23) lists the following six classes of literature: (1) the Six Classics (*jing*), (2) the masters (*zi*), grouped into nine schools, of which the Ru were most prominent, (3) poetry, (4) strategy manuals, (5) the numerical arts and (6) ‘prescriptive techniques’. Much of the philosophical tradition of China is to be found not among the classics but among the masters (*zi*). These works are attributed to individuals to whose surnames the suffix *zi* or ‘Master’ has been added. Recent scholarship has shown that many of these texts are probably of composite authorship and are less the works of individuals than the core texts of ‘schools’ or lineages based on textual transmissions of these works (see Guanzi; Han Feizi;Huainanzi; Mencius; Mozi; Sunzi; Xunzi; Zhuangzi).

By Tang times, the number of classics expanded through the treatment of commentaries and component sections as individual works. The *Yili (Ceremony and Rites)*, *Zhouli (Rites of Zhou)* and the *Liji (Book of Rites)*, works on ritual that had presumably comprised the original *Lijing*, were now treated as separate works. The *Gongyangzhuan (Gongyang Annals)*, *Guliangzhuan (Guliang Annals)* and *Zuozhuan (Zuo Annals)*, three commentary editions of the *Chunqiu*, replaced the original in the classical canon. In addition, the *Erya* was recognized as a classic, as were the *Analects* and *Xiaojing*. During the Song dynasty the *Mengzi* was added, bringing the total to thirteen classics.

3 The thirteen classics

The *Shujing* or *Shangshu* (Book of Documents, or Documents), is a heterogeneous compendium of historical documents. Tradition names Confucius as the editor of this ‘classic’ of Chinese political philosophy, much of which was forged during the fourth century BC. The *Shujing* contains terse accounts of investitures, royal decisions and pronouncements, and ritual dances. It also contains dialogues between kings and ministers, including the advice of ministers to kings, all of which provides some insight into Warring States and Han political philosophy. The *Shujing* contains sections of philosophical exposition on principles of government which could be taken either as a standard of conduct for a discerning and virtuous emperor, or as a guide to conduct for a loyal minister.

The *Yijing (Book of Changes)* consists of an ancient manual of divination of uncertain provenance (the *Zhouyi*, or Zhou Changes) and a group of Warring States period commentaries (the Ten Wings). The divination system employs sixty-four permutations of broken (*yin*) and straight (*yang*) lines combined in six positions. As early as the Han dynasty, the *Yijing* was recognized as foremost among the classics and has functioned as a symbolic language of change and transformation. The *Yijing* provides a theoretical conception of the world as both *sui generis* and in a constant process of change and transformation according to discernible patterns of two complementary forces. The *yin-yang* theory first articulated in the *Yijing* provided the basis for later cosmologies of change and formed part of the foundation of early Daoist thought, medicine and the development of scientific thought in China (see Daoist philosophy; Yijing; Yin-yang).

The *Shijing* is the earliest anthology of poetry in China. According to one tradition, Confucius selected compendium of 305 poems from a larger collection of three thousand poems of popular origin gathered at the Zhou court and dating from the beginning of the Zhou dynasty (tenth century BC) to the middle of the Spring and Autumn period (seventh century BC). It contains four sections of differing geographic origin and contents. The airs (*feng*), a northern collection of songs of community life, farming, feasting and love, preserve a subversive quality of ‘pre-Confucian’ society that at times conflicts with later use by Confucian exegetes. The odes or elegantiae (*ya*) are hunting and banquet songs and political complaints and satires, probably from the Zhou court. The lauds (*song*) are dynastic hymns used in court ceremony and sacrifice. Whatever the authorship of these diverse materials, quotation from the *Shijing* was widely used to support Ruhist argumentation and imperial authority within Han and Warring States texts. The Great Preface to the *Shijing* also contains a remarkable concise formulation of a theory of poetics and aesthetics.

The *Lijing (Classic of Rites, or Three Rites)* is a compendium of Zhou dynasty court religious and social ritual. It consists of three works: the *Zhouli (Rites of Zhou)*, the *Yili (Ceremony and Rites)* and the *Liji (Book of Rites)*. The *Lijing* was the worst preserved of the Five Classics, and the three extant versions of these works on ritual all date from later periods. The *Yili* dates from some time after Confucius, the *Zhouli* dates from the late Warring States period and the extant form of the *Liji* dates from the Han dynasty. The *Yili* provides details of ceremonies from the Spring and Autumn period; it includes detailed descriptions of sacrificial rituals for auspicious occasions, rituals for mourning and funerals, rituals for the reception of guests (including state visits and royal audiences) and rituals for various festive occasions (such as marriage, the capping ceremony for young men, archery contests and the reception of ministers). The *Zhouli* is an idealized description of the Zhou bureaucracy. It describes the ministries that formed the Zhou government, including such topics as the supervision control and appointment of officials, agriculture and marriage, state and religious rites, defense and security, legal administration and public works and civil engineering. It contains many interpolations by Han scholars and is of dubious historical value, but its detailed descriptions provide important insights into early Confucian views of government, law and administration. The *Liji* contains material that ranges in date from the late Warring States to the early Han. It provides information about both ritual and Ruhist philosophy, and contains a variety of Ruhist teachings from the late Zhou through the Han. It also contains essays on general principles of ritual. This section includes two works that the neo-Confucian scholar Zhu Xi established as two of the Confucian Four Books: the *Zhongyong (Doctrine of the Mean)* and the *Daxue (Great Preface)* (see Zhongyong; Daxue). Other sections include descriptions on the regulation of the rites, *yin-yang* theory, mourning, worship and sacrifice, auspicious rites, auspicious occasions and the *Yuejing*.

The *Chunqiu (Spring and Autumn Annals)* is a historical chronicle of the reigns of twelve rulers of the state of Lu. It provides a terse and impersonal factual chronicle of diplomatic and political events from 722-481 BC. According to Mencius, Confucius composed the *Chunqiu* as a historical object lesson of the lawlessness of his own age and his own state of Lu. The Chunqiu was of particular importance because of its use by the Han philosopher Dong Zhongshu, a major formulator of official Han Confucian metaphysics (see Confucian philosophy, Chinese). Dong claimed to have derived his ideas from the *Chunqiu*, and followed Mencius in believing that Confucius, having understood the heavenly patterns that governed the cosmos, applied them to human history. Dong gave Confucius the status of a ‘hidden king’, the moral and metaphysical arbiter whose praise and blame passed correct judgments on the actions of the kings of the past.

The *Chunqiu* was one of the Han dynasty’s Five Classics. From the Tang dynasty onwards it was transmitted through three major commentaries, the *Gongyangzhuan (Gongyang Annals)*, the *Guliangzhuan (Guliang Annals)* and the *Zuozhuan (Zuo Annals)*. The *Guliangzhuan* and *Gongyangzhuan* both use question-and-answer dialogue to provide a morally normative interpretation of the *Chunqiu*. Tradition attributes the origins of the *Gongyangzhuan* to the oral teachings of Zixia, a disciple of Confucius; the *Guliangzhuan* borrows from and elaborates on the *Gongyangzhuan*. Both cover the historical span of the *Chunqiu*, and both employ the ‘praise and blame’ historiography of the latter. The *Zuozhuan* covers a longer period than the other two commentaries (722-453 BC) and contains more historical information. Its date and authorship are the source of considerable controversy.

The *Analects* of Confucius (*Lunyu*) is a collection of anecdotes, sayings and short dialogues, mostly between Confucius and his disciples. While Confucius himself claimed to be a transmitter of Zhou values rather than an innovator, the central concerns of the *Analects* moved away from divination of the will of spirits toward the ethics of the human world and the establishment and maintenance of political and social order. Confucius formulated new notions of humane benevolence (*ren*) and the right conduct of superior individuals (*junzi*) that were to remain hallmarks of later Confucian thought (see Confucian philosophy, Chinese; Confucius).

The *Xiaojing (Book of Filial Piety)* is a short dialogue between Confucius and his disciple Zengzu on filiality towards parents (by their children) and, by analogy, rulers (by their subjects). It is didactic in tone, and describes the virtues of filial piety as ostensibly practised during the golden age of the Zhou. It includes quotations from the *Shijing (Book of Songs)* and is written in question and answer form. The *Xiaojing* was included among the Han seven classics, possibly because its articulation of appropriate behaviour of subjects toward rulers made it an attractive text for imperial patronage. Imperial patronage, as much as philosophical esteem within the tradition, conferred and maintained its status as a classic.

The *Erya* is a dictionary of Zhou terms. Various traditional accounts ascribe it to the Duke of Zhou, Confucius and

the latter's disciple Zixia; recent scholarship dates it to the Qin or early Han dynasty. Its most important influence is in the nineteen categories into which words are grouped. These categories became the basis for the categories of encyclopedias and similar works. While many of the glosses in the *Erya* are cryptic, as a text it contains a variety of 'abstract' terms as well as entries on kinship terms, musical terminology, astronomic and calendrical terms, geographical terms, names of grasses, herbs, trees, wild and domestic animals and legendary animals. It was treated as an authoritative guide to the language of the classics.

The *Mengzi* consists of a series of extended conversations and debates between Mencius and various rulers, opponents and disciples. Mencius developed concepts that had been mentioned or suggested but not developed in the *Analects*. He stressed the inherent goodness of human nature and elaborated a theory of four inherent 'sprouts' of goodness: humane benevolence (*ren*), knowledge or wisdom (*zhi*), ceremony or ritual (*li*) and rectitude (*yi*). Mencius held that these sprouts could, with correct nurture, mature in any individual and create the intuitive ability that is the basis for moral conduct and moral judgment. Mencius also attacked a variety of opponents of Confucius, including the Mohists (see Mohist Philosophy), the followers of Yangzhu and military strategists. The first imperial recognition accorded to the works of Mencius was by the Emperor Wen of the Han dynasty, who established a chair for the study of the *Mengzi*. The *Mengzi* is listed in the Han bibliography among the masters rather than the classics, and only appears in the classical canon during the Song dynasty.

4 Significance

During the approximately fifteen hundred years between Confucius and the Song dynasty, several classical schemata gained and lost sway, including the Six Classics of the Warring States period, the Five Classics of the Han, the Nine Classics of the Tang, and the Thirteen Classics of the Song. Nevertheless, although the content and size of Confucian classical canons changed over time, the notion of classics has been relatively continuous since the beginnings of philosophical thought in China. The classics are of philosophical importance because they articulate central ideas, values and dispositions of Chinese culture. They are also important because the definition of the classical canon effectively excluded other works of considerable philosophical significance.

The Chinese Classics functioned as a classical canon in several senses. First, they provided a textual authority that could serve as a source of intellectual or political authority and legitimation for philosophers and rulers alike. For example, Confucius, Mencius and Xunzi all quote extensively from the *Shijing* and *Shujing*. (Xunzi differs from the other two in that he both quoted poetry as authoritative discourse and composed original verse, and is even listed at the head of a school of poets.)

Second, the classics formed the core of the education system that defined the bureaucratic elite. Despite competing claims from other textual canons and variations in emphasis, these works held a central role in the education (and definition) of the bureaucratic elite. The classical compendia defined the knowledge and the political and moral orientation of a learned scholar or official. Because they formed the root of the state examination system, their mastery was an important prerequisite for political office. Memorizing the classics was a large part of the early intellectual and moral education of boys. Additional 'classics' were developed for the separate education of women. The *Nuxiaojing (Book of Filial Piety for Women)* and the *Nulunyu (Analects for Women)* are both Tang works written by women for the education of women, the latter by a consort of the Tang emperor Dezong in the eighth century. These works were taken as repositories of knowledge, guides to conduct and a repertoire for use in situations that required literary elegance.

Finally, the classics set the philosophical agenda for what came to be known as the early Confucian tradition. They were centrally concerned with two related problems: how to maintain political and social order, and how to persuade rulers to voluntarily limit their own power. As such, all the classics functioned in a strongly hierarchical system and their style of argument or exposition reflects the social context in which they operated, for example, by the prevalence of persuasion over debate.

The thirteen classics are also noteworthy for what they do not contain. Many of the recognized classical works of Chinese philosophy appear in traditional classifications not among the classics but among the masters. Ruhist works include the *Mengzi* (until the Song dynasty) and *Xunzi* (see Mencius; Xunzi). Daoist 'masters' include the *Daodejing* and the *Zhuangzi* (see Daodejing; Zhuangzi). The one surviving Mohist work is the Mohist Canon (see Mohist Philosophy; Mozi); the masters conventionally associated with the so-called Legalist school include Han

Fei, Lord Shang, and Shen Buhai (see Legalist philosophy, Chinese; Han Feizi). Less well-known but important masters include the *Huainanzi* (compiled at the court of Liu An *circa* 140 BC) and the *Lushi chunqiu (Springs and Autumns of Master Lu)*, attributed to Lu Buwei (d. 235 BC) (see Huainanzi).

These works in turn function as the ‘classics’ - in the sense of a master text that defines a school - of several traditions. For example, the *Daodejing*, attributed to the apocryphal sage Laozi but probably dating from about 250 BC, is one of the canonical works of several Daoist traditions and may be the most widely read Chinese text outside China. Still other works, not listed among the masters but titled as classics or masters became the foundational texts for specific schools of expertise, for example, the *Huangdi neijing (Yellow Thearch's Classic of Internal Medicine)*, a medical compendium dating from approximately 100 BC that became the master text for the high textual tradition of Chinese medical practice.

Couvreur, *Cérémonial*, Hsien hsien [Xian Xian]: Imprimerie de la Mission Catholique, 1916; repr. Paris: Cathasia, 1951. (English and French translations respectively of the *Yili*.)

Zhouli (Rites of Zhou) (2nd or 1st century BC), trans. E. Biot, *Le Tcheou-li ou Rites des Tcheou*, Paris: Imprimerie Nationale, 1851; repr. Taipei: Ch'eng-wen, 1975.(French translation of the *Zhouli*.)

Zuozhuan (Zuo Annals) (2nd-1st century BC), trans. J. Legge, *The Ch'un Ts'ew with the Tso Chuen*, in *The Chinese Classics*, vol. 5, 1872; repr. Hong Kong: Hong Kong University Press, 1960; trans. S. Couvreur, *Tch'ouen st'ieou et Tso tschouan*, Ho Kien Fou, 1914, 3 vols; repr. Paris: Cathasia, 1951; trans. B. Watson, *The Tso Chuan: Selections from China's Oldest Narrative History*, New York: Columbia University Press, 1989. (Legge and Couvreur are the English and French translations of the *Chunqiu (Spring and Autumn Annals)* and the *Zuozhuan* commentary. Watson is a new partial translation of the *Zuozhuan*.)

Chinese philosophy

Any attempt to survey an intellectual tradition which encompasses more than four thousand years would be a daunting task even if it could be presumed that the reader shares, at least tacitly, many of the assumptions underlying that tradition. However, no such commonalities can be assumed in attempting to introduce Asian thinking to Western readers. Until the first Jesuit incursions in the late sixteenth century, China had developed in virtual independence of the Indo-European cultural experience and China and the Western world remained in almost complete ignorance of one another.

The dramatic contrast between Chinese and Western modes of philosophic thinking may be illustrated by the fact that the tendency of European philosophers to seek out the being of things, the essential reality lying behind appearances, would meet with little sympathy among Chinese thinkers, whose principal interests lie in the establishment and cultivation of harmonious relationships within their social ambiance. Contrasted with Anglo-European philosophic traditions, the thinking of the Chinese is far more concrete, this-worldly and, above all, practical.

One reason for this difference is suggested by the fact that cosmogonic and cosmological myths played such a minor role in the development of Chinese intellectual culture and that, as a consequence, Chinese eyes were focused not upon issues of cosmic order but upon more mundane questions of how to achieve communal harmony within a relatively small social nexus. The rather profound linguistic and ethnic localism of what Pliny the Elder described as a 'stay-at-home' China, reinforced by a relative freedom from intercultural contact, generated traditional radial communities in which moral, aesthetic and spiritual values could remain relatively implicit and unarticulated. By contrast, in the West these norms had to be abstracted and raised to the level of consciousness to adjudicate conflicts occasioned by the complex ethnic and linguistic interactions associated with the development of a civilization rooted almost from the beginning in the confluence of Greek, Hebrew, and Latin civilizations.

The distinctive origins and histories of Chinese and Western civilizations are manifested in a number of important ways. The priority of logical reasoning in the West is paralleled in China by the prominence of less formal uses of analogical, parabolic and literary discourse. The Chinese are largely indifferent to abstract analyses that seek to maintain an objective perspective, and are decidedly anthropocentric in their motivations for the acquisition, organization and transmission of knowledge. The disinterest in dispassionate speculations upon the nature of things, and a passionate commitment to the goal of social harmony was dominant throughout most of Chinese history. Indeed, the interest in logical speculations on the part of groups such as the sophists and the later Mohists was short-lived in classical China.

The concrete, practical orientation of the Chinese toward the aim of communal harmony conditioned their approach toward philosophical differences. Ideological conflicts were seen, not only by the politicians but by the intellectuals themselves, to threaten societal well-being. Harmonious interaction was finally more important to these thinkers than abstract issues of who had arrived at the 'truth'. Perhaps the most obvious illustration of the way the Chinese handled their theoretical conflicts is to be found in mutual accommodation of the three emergent traditions of Chinese culture, Confucianism, Daoism and Buddhism. Beginning in the Han dynasty (206 BC-AD 220), the diverse themes inherited from the competing 'hundred schools' of pre-imperial China were harmonized within Confucianism as it ascended to become the state ideology. From the Han synthesis until approximately the tenth century AD, strong Buddhist and religious Daoist influences continued to compete with persistent Confucian themes, while from the eleventh century to the modern period, Neoconfucianism - a Chinese neoclassicism - absorbed into itself these existing tensions and those that would emerge as China, like it or not, confronted Western civilization.

In the development of modern China, when Western influence at last seemed a permanent part of Chinese culture, the values of traditional China have remained dominant. For a brief period, intellectual activity surrounding the May Fourth movement in 1919 seemed to be leading the Chinese into directions of Western philosophic interest. Visits by Bertrand Russell and John Dewey, coupled with a large number of Chinese students seeking education in Europe, Great Britain and the USA, promised a new epoch in China's relations with the rest of the world. However, the Marxism that Mao Zedong sponsored in China was 'a Western heresy with which to confront the West'. Mao's Marxism quickly took on a typically 'Chinese' flavour, and China's isolation from Western

intellectual currents continued essentially unabated.

1 Chinese thinking as *ars contextualis*

Our traditional Western senses of order are grounded upon cosmogonic myths that celebrate the victory of an ordered cosmos over chaos. Chaos is a 'yawning gap', a 'gaping void'; it is an emptiness or absence, a nothingness; it is a confused mass of unorganized surds. Hesiod's *Theogony* tells how the yawning gap of Chaos separating Heaven and Earth was overcome by Eros - love thereby creating harmony (see Hesiod). The Book of Genesis tells how, from a 'dark, formless void', order was created by divine command. In the *Timaeus*, Plato's Demiurge 'persuades' the disorganized, intransigent matter into reasonable order, providing 'a victory of persuasion over necessity'. Classical Chinese culture, on the other hand, was little influenced by myths which contrasted an irrational Chaos with an ordered Cosmos. The relative unimportance of cosmogonic myths in China helps to account for the dramatically different intellectual contexts from which the Chinese and Western cultural sensibilities emerged.

In the Western tradition, thinking about the order of things began with questions such as 'What kinds of things are there?' and 'What is the nature (*physis*) of things?' This inquiry, which later came to be called 'metaphysics', took on two principal forms. One, which the scholastics later termed *ontologia generalis* (general ontology), is the investigation of the most essential features of things - the *being* of beings. A slightly less abstract mode of metaphysical thinking, *scientia universalis* (universal science), involves the attempt to construct a science of the sciences, a way of knowing which organizes the various ways of knowing the world about us. Both general ontology and universal science interpret the order of the cosmos. Both suppose that there are general characteristics - the being of beings, or universal principles - which tell us how things are ordered.

Neither of these forms of metaphysical thinking were influential in classical China. One reason for their unimportance is reflected in the character of the Chinese language. Simply put, the classical Chinese language does not employ a copulative verb. The Chinese terms usually used to translate 'being' and 'not-being' are *you* and *wu* (see You-wu). The Chinese *you* means, not that something 'is' (*esse* in Latin) in the sense that it exists in some essential way; it means rather that 'something is present'. 'To be' is 'to be available', 'to be around'. Likewise, *wu* as 'to not be' means 'not to be around'. Thus the Chinese sense of 'being' overlaps 'having'. A familiar line from the Daoist classic the *Laozi* or *Daodejing*, which is often translated 'Not-being is superior to Being', should more responsibly be translated as 'Not-having is superior to having' (or as a Marxist-inspired translator has rendered it, 'Not owning private property is superior to owning private property'). The Chinese language disposes those who employ the notions of *you* and *wu* to concern themselves with the presence or absence of concrete particular things and the effect of having or not having them at hand. Even in recent centuries, when the influence of translating Indo-European culture required the Chinese language to designate a term to do the work of the copula, the choice was *shi*, meaning 'this', thus indicating proximity and availability rather than 'existence'. One must assume that the practical, concrete disposition of Chinese thinkers is both cause and consequence of this characteristic feature of linguistic usage.

Perhaps the best designation for the most general 'science' of order in the Chinese tradition would be *ars contextualis*. 'The art of contextualizing' contrasts with both *scientia universalis* and *ontologia generalis*. Chinese thinkers sought the understanding of order through the artful disposition of things, a participatory process which does not presume that there are essential features, or antecedent-determining principles, serving as transcendent sources of order. The art of contextualizing seeks to understand and appreciate the manner in which particular things present-to-hand are, or may be, most harmoniously correlated. Classical Chinese thinkers located the energy of transformation and change within a world that is *ziran*, autogenerative or literally 'so-of-itself', and found the more or less harmonious interrelations among the particular things around them to be the natural condition of things, requiring no appeal to an ordering principle or agency for explanation.

The dominant Chinese understanding of the order of things advertises an important ambiguity in the notion of 'order' itself. The most familiar understanding of order in the West is associated with uniformity and pattern regularity. This 'logical' or 'rational' ordering is an implication of the cosmological assumptions which characterize the *logos* of a cosmos in terms of causal laws and formal patterns. A second sense of order is characterized by concrete particularities whose uniqueness is essential to the order itself. No final unity is possible in this view since, were this so, the order of the whole would dominate the order of the parts, cancelling the

uniqueness of its constituent particulars. Thus, 'aesthetic' order is ultimately acosmological in the sense that no single order dominates.

The crucial difference between these two senses of order is that in the one case there is the presumption of an objective standard which one perforce must instantiate; in the other, there is no source of order other than the agency of the elements comprising the order. In the West, mathematical order has been thought the purest. In China, by contrast, any notion of order which abstracts from the concrete details of this-worldly existence has been seen as moving in a direction of decreasing relevance. Rational order depends upon the belief in a single-ordered world, a cosmos; aesthetic order speaks of the world in much less unitary terms. In China, the 'cosmos' is simply 'the ten thousand things'. The belief that the things of nature may be ordered in any number of ways is the basis of philosophical thinking as *ars contextualis*.

Each of these understandings of order existed at the beginnings of both Western and Chinese cultures, and both have persisted as interpretative options within them. It so happens that in the course of their respective histories, the two cultures made distinctly different choices which led to the variant senses of order as grounds for the organizing of personal, social and cosmic environs. These differing senses of order are reflected in the fact that the nineteenth-century Japanese had to coin the term *tetsugaku* (philosophy) to translate the Western philosophic tradition and to recover its Japanese counterpart, and that this same expression was soon thereafter imported into China as *zhexue* for the same purpose. The need to invent a term to refer to 'philosophy' suggests at least that these cultures had to reorganize patterns of indigenous intellectual experience in ways previously unfamiliar to them.

2 The dominance of correlative thinking

Rational or logical thinking, grounded in analytic, dialectical and analogical argumentation, stresses the explanatory power of physical causation. In contrast, Chinese thinking depends upon a species of analogy which may be called 'correlative thinking'. Correlative thinking, as it is found both in classical Chinese 'cosmologies' (the *Yijing (Book of Changes)*, Daoism, the Yin-Yang school) and, less importantly, among the classical Greeks involves the association of image or concept-clusters related by meaningful disposition rather than physical causation. Correlative thinking is a species of spontaneous thinking grounded in informal and *ad hoc* analogical procedures presupposing both association and differentiation. The regulative element in this modality of thinking is shared patterns of culture and tradition rather than common assumptions about causal necessity.

The relative indifference of correlative thinking to logical analysis means that the ambiguity, vagueness and incoherence associable with images and metaphors are carried over into the more formal elements of thought. In fact, the chaotic factor in the underdetermined correlative order has a positive value as an opportunity for personalization and self-construal. In contradistinction to the rational mode of thinking which privileges univocity, correlative thinking involves the association of significances into clustered images which are treated as meaning complexes ultimately unanalyzable into any more basic components. In the Western tradition we are familiar with correlations such as those present in the humour theory of medicine, Pythagorean numerical correlations, Kepler's correlation of the perfections of the trinitarian God, the world and the soul, and so forth (see Hippocratic medicine; Pythagoras; Kepler, J.). Astrological charts provide the most familiar illustration of correlative thinking. But, as may be seen particularly (although not exclusively) in the discussion of Daoist philosophy, correlativity is not only an anthropocentric mode of signification. The Daoist notion of *de* - 'particular focus' or 'virtuality' - extends the context of signification to all phenomena (see Daoist philosophy; De).

Correlative thinking is the primary instrument in the creation, organization and transmission of the classical curriculum in China, from the *Book of Songs* to the *Analects* to the *Yijing* (see Chinese Classics; Confucius; Yijing). Perhaps the most overt illustrations of the Chinese resort to correlative thinking in the classical period are to be found in the period of the Han dynasty (206 BC-AD 220). During the Han period, vast tables of correspondences were employed to identify and organize the sorts of things in the natural and social world which were thought to provide a meaningful context for one's life. One such set of tables, called 'tables of five', compared 'the five phases' (wood, fire, earth, metal, water), 'the five directions' (north, east, south, west and centre), 'the five colours' (green, red, yellow, white, black), 'the five notes', and so forth. Other types of correlation employed the twelve months, the twelve pitches, the twenty-eight constellations, the heavenly roots and the earthly branches. Such classifications include body parts, psycho-physical and affective states, styles of

government, weather, domestic animals, technological instruments, heavenly bodies and much more.

One of the important devices for making such correlations is the contrast of *yin* and *yang*, literally, 'the shady side' and 'the sunny side' of the mountain (see Yin-yang). These notions were employed to identify alternative patterns of hierarchical relationship. The old teacher, Laozi, is wiser than his young student and hence 'overshadows' him in this respect. Laozi is *yang* and the student is *yin*. The student, however, is stronger physically than the old master, and hence in physical prowess the student is *yang* to Laozi's *yin*. When these various strengths and weaknesses defining the relationship can be balanced to maximum effect, the relationship is most productive and harmonious. It is clear from this illustration that *yang* and *yin* are by no means to be understood as 'cosmic principles' or ontological contrasts rooted in the very nature of things. Rather, they are heuristics helpful in reading and characterizing the world as concretely experienced in a variety of ways.

Though the contents of many correlative schemata are often *prima facie* the same as the subject matters of the Western natural sciences, there is a crucial difference in the manner they are treated. In China, correlations were not employed as a means of dispassionately investigating the nature of things. Correlative descriptions are, in fact, prescriptions. Correlative schemes oriented human beings in a very practical manner to their external surroundings. Thus, the Chinese were concerned less with astronomy than with astrology; they were far more enthusiastic in the development of geomancy than geology. Science was always understood as ultimately subject to prevailing human values.

3 The organization and transmission of knowledge

The importance of correlative modes of thinking in classical Chinese culture is to be found not only in the acquisition of knowledge but also in its organization and transmission. Plato's employment of the 'Divided Line' allowed for the organization of knowledge by appeal to principles of clarity and coherence which were realized with the achievement of systematic unity (see Plato). Aristotle organized the body of the known into theoretical, practical and productive enterprises by appeal to the nature of the *psyche* as a thinking, acting and feeling creature. In each case there is the appeal to objective principles which serve to articulate the realms of knowledge.

There is a stark contrast between these Western models of classification and the one characteristically found in the traditional *leishu* (encyclopedic or classificatory works) of China. Chinese 'categories' (*lei*) are defined not by the presumption of a shared essence defining natural 'kinds', but by an identified functional similarity or association that obtains among unique particulars. Definitions are not framed in the terms of essential features and formal class membership; instead, definitions tend to be metaphorical and allusive, and invariably entail the human subject and human values. It is the earliest reference in the canons of classical literature, rather than principled scientific explanation grounded in the canons of reason and logic, that holds the weight of authority. In these compendia, there is little interest in the objective description of natural phenomena. The concern instead is with the relationship that the various contents of the world have to the social and cultural values which shape the human experience of it. As an example, the contemporary scholar Liang Congjie points out that 'of the fifty-five sections (*bu*) that make up the *Taiping yulan*, six of them - emperors, imperial relatives, officials, human affairs, ancestors, and ceremony - occupy thirty-five per cent of the work' (Hall and Ames 1995).

These Chinese encyclopedic works are hierarchical, with the human being self-consciously at the centre. Further, this 'human being' is no abstraction but is the specific imperial Chinese person, the emperor, who commissioned the work for the benefit of those examination candidates destined to assist him in governing his empire. Again in each category, individual entries begin from the most noble and conclude with the most base: animals begin from 'lion' and 'elephant' and finish with 'rat' and 'fox'; trees begin with 'pine tree' and 'cypress' and end with 'thistles' and 'brambles'. The world is not described objectively through an articulation of exclusive categories and subcategories, but is divided up prescriptively into natural and cultural elements which have an increasing influence on the experience of the Chinese court as they stand in proximity to the centre. In 'naming' (*ming*) his world, the ruler is 'commanding' (*ming*) it to be a certain way.

As for the transmission of knowledge, we are accustomed to the notion that philosophical ideas are disseminated through debate and dialectical interchange in which one theory or vision confronts another and arguments ensue as to the adequacy of each. However, this manner of looking at the transmission and alteration of ideas does not well suit the Chinese context. This is true primarily because such debate is rooted in rationalistic assumptions of the

sort that privilege theories as relatively coherent patterns of belief and practice, which can be articulated apart from the institutions to which they are relevant. Things were quite different in China. Ancient China overcame the threat of the tensions and conflicts attendant upon ethnic and cultural pluralism by employing the contextualizing force of the Chinese language itself as means of transmitting culture. A class of literati developed; a canon of classical works was compiled and instituted along with a continuing commentarial tradition which served to translate and perpetuate the doctrines of these classical works; an examination system based upon these texts was introduced in the early Han period and persisted with relatively little change for two thousand years, being abolished only as recently as 1905.

With the dominance of Confucian orthodoxy in China, methods of adjudicating doctrinal conflicts were refined in a manner which took as its highest value the maintenance of social stability. Beginning in the early Han period, commentaries upon Confucian texts were produced which vied with each other for proximity to the canonical center. The authors of these commentaries were almost never interested in overthrowing the authority of the canon in favour of their own ideas, but sought to enrich the authority of the classic by claiming to better understand its original meaning. Further, since tradition was the sole ready resource for norms and doctrines, critics of a particular doctrine depended as much as proponents upon a shared cultural repository. This is evidenced in the conventional use of canonical allusions to focus social and political critique. The appeal to canonical authority is again a way of reinforcing a sense of shared community, and stands in sharp contrast to dialectical arguments which reference canons of reason or logic (see Chinese Classics).

Characteristic of scholarly dispute after the emergence of Han orthodoxy is a fundamental commitment to mutual accommodation. There is a general distaste for contentiousness and an active cultivation of the art of accommodation. In the exercise of criticism, the ritual basis of order comes into play since rituals serve as patterns of deference which accommodate and harmonize differences in desires, beliefs and actions. Criticism assumes a context of common concern and becomes thereby a cooperative exercise among responsible participants that proceeds to search for alternatives on which all can agree. One important constraint on self-assertiveness, as well as an encouragement for a consensual resolution, is that critics themselves are always implicated in the existing context; hence, any criticism is ultimately self-referential. Contentiousness, by contrast, betrays a concern for personal advantage. Such self-assertion threatens to disrupt rather than reinforce or improve the harmony of the existing context. From the *Analects* on, an appropriateness (*yi*) which respects social context has been advocated as the positive alternative to self-interested benefit (*li*). The proper goal of critical or constructive expression in China, whether it be scholarly, social or political, is the strengthening of communal harmony.

4 Confucius and Confucianism

While there may be some truth to the claim that in the West, every person is born either a Platonist or an Aristotelian, it is A.N. Whitehead’s apothegm, ‘All of Western philosophy is a series of footnotes to Plato’, that, *mutatis mutandis*, resonates best with the Chinese context. For indeed, all of Chinese thinking is a series of commentaries on Confucius. In fact, the importance of Confucius in China may be said to outshine that of Plato in the Western tradition on at least two grounds. First, there is effectively no sort of pre-Confucian philosophic tradition to match that of the Presocratics. Confucius is not a synthesizer of past *thinkers,* but an interpreter and transmitter of past *institutions*, namely, the idealized Zhou rituals and customs which Confucius thought to be the key to social stability. Second, Confucius’ thinking came to ground the tradition of Chinese culture for practically its entire intellectual tradition, from the early phases of the Han dynasty in the second century BC to at least the beginnings of the Republican period in the early twentieth century, and arguably down to the present day in a decidedly Chinese form of Marxism (see Marxism, Chinese).

The philosophy of Confucius begins from some basic assumptions, several of which can be derived from the following passage from the *Analects*:

> The Master said: ‘Lead the people with administrative injunctions and put them in their place with penal law, and they will avoid punishments but will be without a sense of shame. Lead them with excellence and put them in their place through roles and ritual practices, and in addition to developing a sense of shame, will order themselves harmoniously.’

(*Analects* 2/3)

First, Confucius believed in the radical malleability of the nascent human being through education and cultivation (see Self-cultivation in Chinese philosophy). Humanity for Confucius is not defined by anything 'given'; there is no essential human nature. Becoming human is a cultural achievement. Second, the formal instrument for pursuing personal refinement and self-articulation is *li*, often translated as ritual practice or propriety (see Law and ritual in Chinese philosophy). Propriety, which includes everything from etiquette to social roles and institutions to the rites of life and death, is the underlying syntax of community. These formal structures reside in the conduct of those members of the community who serve as models of propriety.

The ultimate value of human experience lies in 'becoming a quality person' (*ren*), where the character which represents this accomplishment is constituted by 'person' and the numeral, 'two', suggesting its fundamentally social nature. It is because a person is shaped and articulated as a specific complex of roles and relationships that the Confucian person is irreducibly social. This social definition of person makes the promise of communal approbation an important encouragement for proper conduct, and the threat of shame an equally effective deterrent against undesirable conduct. Further, communal living becomes increasingly meaningful through the deepening quality of those particular relationships which constitute it: *this* person's son, *that* person's husband, *this* person's neighbour.

The goal of overcoming selfishness, fundamental in classical Confucianism, is not designed to be altruistic. The premise here is that selfishness is the greatest obstacle to the realization of one's social self. Since personal, familial, communal, political and even cosmic order are all coterminous and mutually entailing, commitment to community, far from being self-abnegating, is the road to personal fulfillment.

Excellence or virtue (*de*) achieved by members of the community empowers them as likely models of propriety for succeeding generations. Because the authority of community so constructed is internal to it, the community is self-regulating, dependent for its effectiveness upon authoritative leaders rather than the application of some external apparatus such as law and punishment. It is well worth noting that the importance of exemplary models of propriety in a Confucian society contrasts readily with the stress upon the resort to ethical principles so typical of rationalized societies. In the West, exemplary persons - Socrates or St Francis - are not typically thought to be ends in themselves; their lives point beyond to transcendent realities which ground their virtues. In Confucian societies, however, the sage Kings Yao and Shun, the Duke of Zhou - and Confucius himself - are self-realized individuals who serve as distinctly immanent and historical individuals whose lives constitute models for emulation.

The distinction between a society of principles and a society shaped by models of propriety helps us to understand the distinctly 'aesthetic' quality of Confucian morality. Propriety leads to 'proper' conduct in one's relationships by at once reinforcing traditionally appropriate norms while at the same time insisting that they be internalized and 'made one's own' (*yi*). The notion of propriety or 'rightness' (*yi*) in a Confucian society, since it applies always within a social context, must involve notions of 'harmony'. Proper actions are 'fitting' in the sense that they fit and harmonize with other such actions. The notion of the 'right' action, therefore, has much in common with the artist's choice of the 'right' brush or the 'right' colour in the execution of a painting.

The failure to understand the aesthetic character of Confucian ethics has reinforced the tendency for Western philosophers to understand Confucian ritualization (*li*) as the imposition of external guides to conduct, mere forms imposed upon one from outside. Hegel's depiction of China as a culture without *Geist* in his *Philosophy of History* is representative of interpretations by the best minds of Europe and America. This truncated reading has in turn perpetuated the stereotypical opinion of Confucius as a purveyor of trite moral truisms, rather than as a founder of a social order which, by its dependence upon the sort of balanced complexity associated with aesthetic creations, has lasted longer than any other on the face of the planet.

5 Philosophical Daoism

Daoism is a complex movement in early China (see Daoist philosophy). A proto-Daoist religious sensibility seems to have been a stratum of Chinese popular culture centuries before the emergence of 'religious Daoism' as a formal iconoclastic movement in the second century AD. During the late Warring States period, Daoism developed a sublimated and sophisticated intellectual dimension as a response to rival traditions of thought. Because this school of political and philosophical anarchism was articulated in two primary compilations, the *Daodejing* (or *Laozi*) and the *Zhuangzi*, it came to be known as 'Lao-Zhuang' Daoism (see Daodejing and Zhuangzi).

The central message of this school is captured by the title of the *Daodejing* - literally, 'the classic of *dao* and *de*'. In fact, the name '*dao*-ism' itself is an abbreviation of the earliest designation of this tradition as '*dao-de*-ism', reflecting the core question which pervades the Daoist texts: what is the relationship between *dao* and *de*? This can be interpreted and restated as: what constitutes excellence (*de*) and how does one achieve it within one's particular place (*de*) in the world (*dao*)? Since one's 'place' is both spatial and temporal, de is the excellence achieved as one treads one's 'pathway' (or *dao*) through life (see Dao; De).

A central Lao-Zhuang complaint against rival Confucianism is ecological, denouncing the anthropocentric limits it imposes on personal realization. While early Confucianism argues that human beings are the product of harmoniously orchestrated interpersonal relationships, the Daoists insist that the relational definition of humanity be extended to encompass the world more broadly. Human beings inhere in social, cultural *and* natural environments, and these environments are continuous and mutually shaping. The rhythm and regularity of human community is embedded in, and hence must be responsive to, the cadence and flow of all of nature's complex orders. To ignore the responsibility of humanity to participate fully in the harmony of our non-human surroundings leads inevitably to the distortion of our natural impulses by the imposition of often ossified conventions and institutions on the intuitive ground of human experience. Impositional conduct leads to coercion which, in the human world as our most immediate example, reduces the creative possibilities of community by denying the full participation of some of its participants.

The *Daodejing* expresses this notion of teasing an integrated and dynamic harmony out of available differences: 'The myriad things shoulder *yin* and embrace *yang* and blend their energies (*qi*) together to constitute a harmony (*he*)' (see Qi). The 'myriad things' denotes the natural world as a complex of unique and particular thing-events (*de*). This complex of things lacks the suggestion of a single-ordered unity or coherence carried by terms such as 'cosmos' or 'universe', where the inventory of things is thought to be organized according to unifying natural laws and causal relationships. To the extent that the myriad things achieve 'order', it is constituted by the sum of a contingent set of aesthetic harmonies construed from the perspective of each of the participants as they dispose and express themselves in the world.

The intelligible patterns created by the many different things which collaborate to constitute the world are all pathways or *dao*s which can, in varying degrees, be traced out to map one's own place and its context, and in this mapping, to find coherence and meaning. *Dao* is always reflexive in that there is no final distinction between an independent source of order and that which it orders. One's world and its order are constituted by the collaboration of oneself with a myriad other self-causing and mutually shaping particulars. *Dao* is, at any given time and place, both *what* the world is and *how* it is, as entertained from that perspective. For this reason, from a human point of view, explanation does not lie in the discovery of some antecedent agency or the isolation and disclosure of relevant causes. Rather, any particular event or phenomenon can be understood by mapping out the conditions which collaborate to sponsor it. Once broadly understood, these same conditions can be manipulated therapeutically to anticipate the next moment, and to prescribe for it.

The *Daodejing* is primarily a political treatise. It is by bringing this anarchic and ecological sensibility to the operations of human governance that government in its relationship to community can become *wuwei*, free of any coercive activity and free to orchestrate the full talents of its constituent population (see Daodejing).

The *Zhuangzi*, focusing more on personal than political realization, is without question one of the richest and most celebrated pieces of philosophical literature in the Chinese tradition. While expressing an unrelenting scepticism about those evidential claims for certainty and objectivity which empower competing philosophical voices, this text uses a collage of anecdotes, parables, provocative images and other such rhetorical tropes and strategies to defend creativity as a fundamental value. It is through an appreciation of the role of creativity in the world that one comes to an understanding of an inclusively 'proper' order, where the 'anarchic' harmony, eschewing as it does any sense of determinative principle or *archē*, is 'made mine' by the fullest expression of all participating elements. The functional value of such an anarchic understanding of order in the world lies in overcoming any fear of personal injury or death by recognizing and relying upon the discernible regularity and continuity in the world, and by respecting the contribution that transformative change makes to the quality of life (see Zhuangzi).

Daoism, like Confucianism, becomes porous and eclectic as it enters the Han dynasty, and serves as a freewheeling counterpoint to the Confucian state ideology throughout the two millennia of Imperial China. In the

Huainanzi, an early Han compendium of knowledge representative of this syncretic turn, Daoism serves as a primary ore, being alloyed with the concerns and perspectives of competing schools to produce a more malleable and practical amalgam. The coherence of the *Huainanzi*, however, is one true to the spirit of Lao-Zhuang in that conflicting and divided opinions are happily juxtaposed as necessary for providing the fullest summary of China's cultural achievements. It is richness and intensity rather than some rationalized order that is the signature of Huainanzi's version of syncretic Daoism (see Huainanzi).

There were also 'Huang-Lao' Daoists in late Qin and Eastern Han dynasties who combined the seemingly incompatible bureaucratic and technocratic designs associated with the Yellow Emperor (Huangdi) with Daoistic sensibilities as a strategy for participating effectively in the political order. These thinkers coupled the institutional structures and institutions of centralized government with Daoist notions of sagely government to constitute a kind of instrumental Daoism. Recent archaeological discoveries are providing an increasing amount of evidence from which to bring this movement into clearer focus.

The qualitative, aesthetic concerns which pervade Daoism continued to have an important influence throughout the evolution of Chinese culture, most notably in the productive and literary arts: painting, calligraphy, poetry, ceramics and so on. The vocabulary of Daoism was also instrumental in transforming imported Mahāyāna Buddhism from an exotic religion into a source of spiritual growth with largely indigenous aspirations (see Buddhist philosophy, Chinese).

6 The 'Hundred Schools'

Granted the disposition on the part of the Chinese to promote a harmonious narrative of China's cultural development, a closer look at the actual events yields a slightly greater sense of conflict. In the approximately one hundred years intervening between the death of Confucius in 481 BC and the birth of his most influential disciple, Mencius, in *circa* 380 BC, a complex variety of philosophical schools developed. In the Daoist work the *Zhuangzi*, this growth in diversity is referred to as the period of the 'Hundred Schools'. Far from seeing in this a healthy pluralism of opinion, the *Mengzi* (3B/9), as a representative of the Confucian tradition, described this phenomenon in the most negative of terms: 'Sage-kings do not arise, the various nobles do as they please, scholars without position speak freely on any number of topics, and the words of Yang Zhu and Mo Di fill the empire.'

The period of the conflicting schools began when Mo Di, the founder of Mohism, called Confucian ideas into question. Mohist thinking, generally characterized as a kind of utilitarianism, constituted a significant challenge to the ritually grounded traditionalism of Confucius (see Mohist philosophy; Mozi; Logic in China). Legalism, associated with Shang Yang (d. 338 BC) and Han Feizi, differed from both Confucianism and Mohism by beginning its social thinking not with the people but with positive laws and sanctions presumed to be external devices necessary to bring order to the turmoil of its day. With the Legalists came at least the adumbration of a theory of rational political order (see Legalist philosophy, Chinese; Law and ritual in Chinese philosophy). During the succeeding centuries leading up to the founding of the Han dynasty, a plethora of alternative schools emerged and court-sponsored academies were established in different parts of the empire reminiscent of the great academies of classical Greece. The most famous representative of these academies during the fourth and early third centuries was Jixia at the Qi capital of Linzi, attracting over time a range of such notables as Zhuangzi, Song Xing, Shen Dao, Mencius, Gaozi, Xunzi and Zou Yan.

In the beginning, the competing schools engaged primarily in debates over doctrine, although they were also quite ready to offer commentary on the ever changing political situation. Conservative Confucians who sought the meaning of life by appeal to family and social obligations were opposed by those Daoists who sought to attune the human world to the regular rhythms and patterns of nature. There were fierce debates among the Confucians, Daoists, Mohists, Sophists and Yangists (and many others) concerning the goodness or evil or neutrality of human nature. In due course, as the contest became increasingly complex, the debates took a procedural and logical turn. Thinkers such as Zhuangzi, Sophists such as Hui Shi and Gongsun Longzi and the later Mohist logicians began to argue about the meaning of argument itself, and to worry over standards of evidence. Mohism and the School of Names developed a complex and technical vocabulary for disputation, and puzzled over the linguistic paradoxes which advertise the limits of language (see Logic in China). Thus, as was the case in the history of early Greek thinking, a second-order rationalism developed in China primarily as a means of adjudicating doctrinal conflict.

One of the most puzzling questions in Chinese intellectual history is why the rational and proto-scientific activities illustrated by the disputations of the late fourth and third centuries BC had virtually vanished by the early years of the Han dynasty. Perhaps the most plausible explanation for this phenomenon is one best couched in terms of the sociology of knowledge. As noted above in our discussions on the transmission of knowledge in China, the civilizing process in China was not one of urbanization as in the West, where the very word 'civilization' means 'citification'. Politics was explicitly concerned with the *polis*, and thus had to confront the complex patterns of trade and commerce associated with interactions among diverse languages and ethnicities, along with the growth of a plurality of institutions - banks, universities, trading companies - each with its own ideological axe to grind. Politics then became the art of compromise applied essentially to pluralistic urban centers.

In China, civilization was effected by the contextualizing power of a common written language. Thus, the same logical tools which could effectively serve the cause of adjudicating disputes in a pluralistic urban society such as developed in Europe would be unacceptably disruptive in a society whose stability was dependent upon the existence of communal affect associated with a common literature which both shaped and was shaped by a common language. The art historian George Rowley once remarked that for the Chinese, truth is not truth unless it is subtle. This is but to say that the bare bones logical propositions, bereft of subjective forms of feeling, cannot be 'true'. The affective and connotative features of language must always be present if language is to serve its function of harmonizing and stabilizing social interactions.

Herein lies a productive illustration of the greatest of contrasts between the politics of China and of the West. For the Western cultures, which are characterized by a pluralism of beliefs and practices, logical tools are essential as instruments of conflict resolution. For the Chinese culture, characterized by a far greater homogeneity of language and ethnicity, those same tools threaten the community of affect which guarantees social harmony. Thus in China, the seeds of 'rationalism' and the contentiousness it entails could be expected to have fallen upon rocky soil, and indeed they did.

7 Xunxi and rationalized Confucianism

A decisive figure in both the emergence and ultimate decline of rationalism in early China was the Confucian philosopher Xunzi. Xunzi is often touted as the most 'rationalistic' of the classical Confucians, and in one sense he deserves to be so described. However, because his so-called rationalism is grounded in history and culture without appeal to metaphysical, grammatical or sociological determinants, he is rationalistic in a rather Pickwickian sense. Xunzi's project does not illustrate a development of the incipient rationalism of the later Mohists and the School of Names. His is a distinctly historicist programme - and a historicist rationalism is, strictly speaking, oxymoronic. Thus in an analysis of argumentation in Xunzi, one must distinguish Xunzi's concrete, historical rationality from notions of abstract and impersonal reason familiar in classical Western metaphysical thinking.

There is, in spite of many similarities, also a fundamental difference between Xunzi's rationality and the peculiar kind of reasoning which grounds the later Mohist *Canons*. The rationality shared by Xunzi and the later Mohists is based upon their nominalist stances. However, the almost total congruence between the later Mohists and Xunzi on the nature of language and logic, which among other things allows Xunzi to utilize most of the technical vocabulary of the Mohist disputers, must be qualified by the fact that Mohist nominalism shares with physicalist nominalism of the Western tradition the importance of logical (and causal) necessity (see Nominalism). For the Mohists, necessity (*bi*) is what is 'unending' (*bu yi ye*), a condition of logical and scientific disputation which is invulnerable to time. Thus, even though the later Mohist has no explicit metaphysical theory, there is a belief that the world is comprised by concrete particulars with necessary logical relations one to the other (see Mohist philosophy).

By contrast, there are no metaphysical, linguistic or behaviourial determinants to be found in Xunzi. Rationality for Xunzi is formed dialectically amid cultural, social and natural forces, both shaping and being shaped by them. Valid reasoning is the discovery and articulation of appropriate and efficacious historical instances of reasonableness. 'Reasoning' (*li*) and historical analogy are inseparable (see Li). On the one hand, *li* - the mapping out of patterns - can only operate on the basis of assumed classifications (*lei*); at the same time, it is the 'mapping' operation of *li*, including and excluding on the basis of perceived similarities and differences, that establishes classifications (*lei*) in the first place.

Xunzi's nominalism must be understood, much as that of the Greek Sophists, as a tropic rather than a metaphysical device. Nominalism of the 'rhetorical' as opposed to the 'logical' or 'atomistic' variety does not arise from a conviction that universals do not exist, or that there are no abstract entities, or that there are no such things as non-individuals. Xunzi's rhetorical or linguistic nominalism is essentially an anti-metaphysical and an anti-logical methodology that is quite similar to the sophistic nominalisms of many of the early Greek rhetoricians.

Though Mencius was later to emerge in the Chinese tradition as the most prominent of Confucius's interpreters, it was Xunzi's ritual-centred Confucianism that held sway in the formative years of Confucianism as a state ideology. This was emphatically the case during the first century of the Han dynasty and the founding of empire. The institutionalization of academic positions which the Han dynasty inherited from the Qin helped to perpetuate and galvanize the influence of Xunzi. Several of Xunzi's immediate students were responsible for the transmission of specific classics which comprised the Confucian curriculum, including the *Guliang Commentary* to the *Spring and Autumn Annals* and the *Zuozhuan* historical narrative. Even the 'Mao' orthodox version of the *Book of Songs* was named for a lineage of Xunzi disciples. The preface to Xunzi's collected works written two hundred years after his death by the court bibliographer Liu Xiang (79-8 BC), reported that Lanling, still under the influence of Xunzi, continued to produce fine scholars.

Perhaps Xunzi's greatest and most enduring influence came from the extent to which he continued Confucius' emphasis on ritual practice as an instrument for socializing, enculturating and humanizing the Chinese world. His description of the function of ritual in society is cited extensively in the histories and the many canons of ritual that were compiled during this period, and looms large in the syncretic philosophical literature that was to become the signature of the Han. The *Huainanzi*, for example, is by and large a text representing a variety of often conflicting philosophical positions, but the crown of this Han dynasty work is its final chapter, the 'Greatest Clan' (*taizu*), which develops a philosophical position in many aspects reminiscent of Xunzi, especially with respect to the importance of ritual and learning (see Huainanzi).

It can be argued that Xunzi, by co-opting the philosophic concerns of the early rationalists for the emerging Confucian program, made the formal continuation of these competing schools redundant. Put another way, the nascent rationalism which was emerging in those thinkers interested in argument for its own sake was overwhelmed by the conventionalist rationalism of Xunzi and the large following he attracted in the early years of the Han dynasty. The signature of the Confucian sense of order that persists far beyond the temporal borders of the Han dynasty is typified by Xunzi's ritually constituted community, a movement from contesting diversity to an absorbent and inclusive harmony. The emergence of what we might call 'Han' thinking in this period had a determinative effect on the style which Chinese philosophy was to assume throughout its long history.

8 First millennium syncretism

With the emergence of a Confucian orthodoxy in the Han dynasty based on the Xunzi branch of Confucianism, scholarly dispute was tempered by a fundamental commitment to mutual accommodation. In the exercise of criticism the ritual basis of order comes into play, since rituals serve as patterns of deference which accommodate and harmonize differences in desires, attitudes and actions. Ideally, 'dispute' is a cooperative exercise among responsible participants that proceeds beyond obstinacy to search for alternatives on which all can agree. There is a fundamental dis-esteem for coercion of any kind, because aggressiveness or violence threatens to disrupt rather than reinforce or improve upon the existing social order. The goal of protest is not victory in contest, which is necessarily divisive, but the strengthening of communal harmony.

The interest in logic and rationality as tools of disputation which had emerged briefly in the pre-Qin days of the Hundred Schools, along with the analytical and dialectical modes of discourse attendant upon these methodologies, soon faded into the counter-current of Chinese intellectual culture. With the ascent of a Confucian ideology, China emerged as a culture grounded in the immanent aesthetic order of a ritually-constituted society, in large measure precluding the kind of rational conflict familiar in the Western tradition. With the Han thinkers came the emergence of a fortified Confucian orthodoxy, complete with canon and commentary.

By the beginning of the first century BC, Confucianism had become the clear and enduring victor over all contending voices, a success due in important degree to its ability to accommodate within a ritually-grounded intellectual society the most profound elements of Daoism, Legalism and Mohism, a pattern that would be repeated

in Confucianism's gradual appropriation of Buddhist elements by its medieval adherents. It is generally recognized that the intellectual orthodoxy which came to dominance in the Han dynasty was a river fed by three powerful streams: Confucianism, Daoism and Buddhism. The stress here is upon the harmony of the three traditions. Though Confucianism remains dominant, the three sensibilities provide distinct foci in accordance with which one can construe one's life.

Confucians are often distinguished from Daoists by the observation that though both seek aesthetic harmony, the Daoists seek harmony with nature while Confucians are concerned with harmony in the social sphere. 'Nature' ('the ten thousand things') and 'society', as contexts, are both aesthetic products whose order is a creation of the elements of the contexts (see Aesthetics, Chinese). In the Daoist text the *Zhuangzi*, there is the statement that each of the ten thousand things comes into being out of its own inner reflection and yet none can tell how it comes to be so. The Confucian version of this claim is that 'it is the person who extends order in the world (*dao*), not order that extends the person' (*Analects* 15/29).

In China, the phrase 'the continuity between man and Heaven' (*tianren heyi*) has been construed to mean that personal, societal, political and cosmic order are coterminous and mutually entailing, and that from the human perspective, this order is emergent in the process of one's own self-cultivation and articulation. If we think of the various contexts which are to be harmonized as concentric circles, we can see that there is an interdependence between one's self-realization at the center and world order at the outer extreme. Classically, this is expressed through the notion of the Sage as exemplar both of tradition in its broadest sense and 'the will of Heaven' - that is, the specific environing conditions that set up the viable possibilities in a particular social situation or historical epoch. This is the sense of Mencius' assertions that 'all of the myriad things are complete here in me' and 'one who applies exhaustively his heart-and-mind realizes his character, and in thus realizing his character, realizes Heaven (*tian*)' (*Mengzi* 7A/4 and 7A/1).

There are continuous and dynamic patterns discernable in the developmental flow of Chinese philosophy that provide us with a way of organizing the tradition beyond its consolidation in the Han dynasty. First, the membrane that divides Chinese intellectual culture into 'schools' and 'traditions' is highly porous. Intellectual diversity, like political diversity, follows a pattern of being absorbed and assimilated into a harmony dominated by some central doctrine, and then precipitating out of this same harmony in periods of disunity. When the centre is strong, the dominant school draws into itself and co-opts competing elements, thereby fortifying itself against opposition. When, over time, the centre weakens, disintegration sets in and those intellectual resources that have been marginalized by the dominant centre move in to reshape the core.

As noted above, Confucianism, fortified by precepts and concerns drawn from the 'Hundred Schools' of the pre-Qin period, emerges as the prevailing Han ideology. As the Han dynasty declines in the second century AD, religious Daoism and Buddhism move in from the periphery to recolour the intellectual ideology, transforming state-centred Confucianism into the more esoteric and reclusive 'pure conversation' (*qingtan*) and neo-Daoist (*xuanxue*) movements of the Northern and Southern dynasties. However, the influence is mutual. As Buddhism takes root and flourishes in Chinese soil, it is interpreted through indigenous categories which overwhelm many of its original concerns, gradually translating it into a religion and philosophy consonant with the assumptions of the Sinitic world view. By the time the Huayan and Chan sects of Buddhism appear in the Tang dynasty (see Buddhist philosophy, Chinese), doctrinal affinities with Daoism and Confucianism have transformed an erstwhile foreign doctrine into a Chinese institution.

9 Neo-Confucianism: Zhu Xi and Wang Yangming

As the Empire regrouped and neo-Confucianism (see Neo-Confucian philosophy), referred to as '*dao* learning' in Chinese, began to take shape in the medieval period, the speculative and the practical extremes of Buddhism came to exert an influence on the revival of Confucianism and to set the agenda for rival claims to orthodoxy within the neo-Confucian ranks. On one extreme, the Cheng-Zhu school favoured broad text-based learning and 'the investigation of things' (*gewu*) while the competing Lu-Wang school rejected canonical studies for a more subjective, meditative approach to personal realization. What these contesting traditions shared in common was philosophical ambition encouraged by the presumption that there is a direct line between personal cultivation and an understanding of natural and moral order. This led to extended reflections on the nature and order of all things, and heated discussions about the relationships that obtained among the most abstract distinctions which could be

marshalled in explanation of cosmic regularities. Where these two extremes of neo-Confucianism disagreed most fundamentally was on the most effective method of self-cultivation (see Self-cultivation in Chinese philosophy).

Zhu Xi is representative of the systematic and theoretical wing of neo-Confucianism. His extensive commentaries established the Four Books (the *Analects*, the *Mengzi*, the *Daxue (Great Learning)* and the *Zhongyong (Doctrine of the Mean)*) as the core curriculum for official examinations, an orthodoxy that persisted into the twentieth century. The authority of Zhu Xi's project lay in his claim to retrieve and revive the import of classical Confucianism. In so doing, he made use of the traditional philosophical vocabulary, but augmented it with complex theoretical discussions of *li* (the patterned regularity of existence) and *qi* (the psychosomatic stuff of existence), giving precedence to the former as identical with the grounding principle of Zhou Dunyi's cosmology, the Great Ultimate (*taiji*) (see Li; Qi; Zhou Dunyi). Hence, Zhu Xi's wing of neo-Confucianism is often referred to as '*li* learning'. These abstract distinctions had moral significance. They could be appealed to qualitatively in explanation of both the goodness of humanity and how to realize it. Although Zhu Xi did not rule out introspection as a means to illumination, the emphasis of his programme was clearly on scholarly learning.

The most eminent of the thinkers representing an emphasis upon internal cultivation was Wang Yangming. He rejected the intellectualization of personal realization by identifying the heart-and-mind (see Xin (heart-and-mind)) with *li*, or pattern. For Wang, the human mind is both the locus and the standard of sagehood. Perhaps the most celebrated theme in Wang is his belief in the continuity and inseparability of knowledge and practice.

There is some question among contemporary scholars as to whether neo-Confucian philosophy, launched with the eleventh century cosmological speculations of Shao Yong and Zhou Dunyi, abandoned the tradition of *ars contextualis* and became metaphysical in a more recognizably Western sense. This involves the question as to whether notions of 'transcendence', 'objective essences' and 'natural kinds' were at least tacitly introduced. At the very least, one can say that Western philosophers would find the language of neo-Confucian philosophers more familiar than that of most other Chinese thinkers. Having allowed this surface familiarity, one must consider that the philosophical substance of tradition weighs heavily against any assumption that neo-Confucianism was dualistic, and was thus disposed to move in an essentialist direction.

Historically, the speculative, cosmological turn in Chinese philosophy came under formidable attack with the founding of the Qing dynasty in the seventeenth century. Evidential research (*kaozhengxue*) brought with it an attempt to get behind the 'empty' commentaries of neo-Confucianism and a return to the philologically-centered historical scholarship of 'Han learning' (*Hanxue*). On the premise that new problems require new solutions, the abstract theorizing and universalistic tendencies of Song-Ming '*dao* learning' gave way to the analysis of particular historical events and cultural artifacts as a resource for finding answers to the specific issues of the day. Thinkers such as Wang Fuzhi and Dai Zhen recovered and reaffirmed the correlative and interdependent relationship between historical event and the principles of order. Once again, it can be seen how the pragmatic concerns of most Chinese intellectuals militate against the exercise of philosophical speculations that move too far afield from the concrete problems of human beings, or which could conceivably serve to introduce contentiousness among intellectuals.

10 The modern period

Beginning with the Buddhist incursion into China at the beginning of the Common Era, the question of the degree to which 'Western' influences have effected significant changes in China's cultural life has been vigorously debated. Han Yu, like Mencius a thousand years earlier, railed against the pernicious influence upon the Confucian community of competing ideologies. Yet, as we have argued above, the Chinese genius for realizing social stability through the harmonious integration of novel influences led to the effective transformation of Buddhist ideology and practice into a distinctly Chinese institution.

In modern times, events surrounding the May Fourth movement in 1919 seemed likely to lead to the Chinese acceptance of Western ideological influences. Hu Shi, a student of John Dewey and later a distinguished Chinese philosopher, helped arrange Dewey's twenty-six month lecture tour of China in 1919-21), and later sought to disseminate his mentor's ideas. Bertrand Russell, whose lectures in China overlapped Dewey's, was equally well-received by the intelligentsia. However, the final result of the May Fourth uprising, which occurred just three days after Dewey's arrival in China, was not the realization of democratic reform but the founding of the Chinese

Communist Party in 1921. The widespread assumption that Marxism has effectively westernized Chinese philosophical culture is seriously challenged by Mao's own claim, upon adopting Marxist ideology, that he was using a Western heresy to confront the West (see Marxism, Chinese).

The Chinese transformation of Marxist into Maoist thinking in contemporary China reveals the inertia of Chinese tradition. The single most distinctive change that Mao made to Marxism was a commitment to particularity and site-specificity. Dialectical materialism is revised to reflect a *yin-yang ad hoc* relationship between economic principle and social superstructure. Although hierarchical, these forces are seen as interdependent and mutually determining. Human malleability and the fluidity of social nature goes far beyond the standard Marxian line. Where Marx places emphasis on the uniformity of class-originated nature, Mao emphasizes the importance of those differences derived from ways of living and thinking that must be factored into the evaluation of any particular 'concrete' personality. There is in Mao a basic suspicion of abstract, general claims, and a recurrent return to specific cases and historical examples. The contemporary Chinese view so historicizes the Marxist sensibility as to make room for an almost unlimited flexibility with regard to the shaping of individual personalities and the development of individual skills (see Marxism, Chinese).

There is little evidence to suggest that contemporary China has abandoned any significant elements of its syncretic Confucian orthodoxy. The dynastic leadership of contemporary China maintains many of the same characteristics that have dominated since the Han dynasty: a governing state ideology that gives all people their respective place in their community, an understanding of the nation as a 'family', a programmatic constitution which functions more like a Bill of 'Rites' than a Bill of Rights, a filial respect for the ruler as 'father and mother' of the people, and the consequent sense of rule as a personal exercise. With respect to the personal character of rule, it continues to be the case in China that to object to the policies that articulate the existing order is in fact to condemn the ruler's person.

As a ritually-constituted society, without grounding in the objective principles associated with reason or natural law, contemporary China is defined by the exemplars of its tradition. The members of the society are themselves possessed of their 'humanity' not as a gift from God or a common genetic inheritance, but as created by ritual enactment. The Chinese have no inalienable rights. Citizens have been deemed to possess only those rights granted by China's various constitutions. The Chinese would see the Enlightenment insistence upon the universality of certain values and principles as an instance of ethnocentric dogmatism. Chinese ethnocentrism is, perhaps, more consistent than its Western counterpart since it is grounded in the self-conscious insistence upon the centrality of its peculiar ethos, defined by racial and linguistic identity.

China remains a culture grounded in the model of the family which cultivates filial dependency. Thus, the Chinese have no means of cultivating that 'healthy suspicion' of governmental power which we take for granted without undermining the community of affect that binds ruler and people. As a rational means of organizing social and economic interactions, the technology so prized in the West cannot but erode the ritual grounding of interpersonal relationships. One of the catchwords of the Tiananmen protests in 1989 was 'democracy'. But, in a society where individualism remains a symptom of selfishness and license, and freedom of speech must be qualified by the Confucian understanding that not only saying but *thinking* involves a disposition to act, Chinese democracy must certainly take on an unfamiliar form. Indeed, the inhibition of individualism and freedom of speech is not a modern invention of Chinese communists but a persistent feature of a Confucian society in which ideas are always dispositions to act.

One can hardly look closely at the intellectual culture of contemporary China without coming to respect the power of China's traditions. The intransigent sense of 'Chineseness' which coalesced in the Han dynasty continues to determine the shape of Chinese intellectual culture. For good or ill, the Chinese remain the people of the Han.

Chinese room argument

John Searle's 'Chinese room' argument aims to refute 'strong AI' (artificial intelligence), the view that instantiating a computer program is sufficient for having contentful mental states. Imagine a program that produces conversationally appropriate Chinese responses to Chinese utterances. Suppose Searle, who understands no Chinese, sits in a room and is passed slips of paper bearing strings of shapes which, unbeknown to him, are Chinese sentences. Searle performs the formal manipulations of the program and passes back slips bearing conversationally appropriate Chinese responses. Searle seems to instantiate the program, but understands no Chinese. So, Searle concludes, strong AI is false.

Searle (1980) argues that, since in the imaginary case he does everything the computer would do and he still does not understand a word of Chinese, it follows that a computer successfully programmed to pass a Chinese Turing test (see Turing, A.M. §3) would not understand Chinese either. The problem, according to Searle, is that computer programs, whether executed by electronic devices or by Searle inside the room, concern only *syntax*, or strings of symbols characterized only by *spelling*, not *meaning*, while thought and understanding require meaning and semantics. And he claims you cannot get semantics from mere syntax, no matter how subtle or complicated it may be.

An underlying assumption of Searle's interpretation is that real mentality and genuine intentional content (what he calls 'intrinsic intentionality') require consciousness. In later publications Searle (1990a) has made this explicit in terms of his 'connection principle', which states that the notion of an unconscious or non-conscious thought can be coherently understood only as a disposition to have a corresponding conscious thought; an unconscious belief that *p* or desire for *x* is nothing more than the disposition to have a conscious belief that *p* or desire for *x* under apt circumstances. He argues that the notion of a thought that is in principle inaccessible to consciousness is incoherent (see Unconscious mental states §5).

Many objections have been raised against the Chinese room. Searle pre-emptively discussed and tried to refute several of them at the time of his original publication. Two have been especially important: those which Searle labels the 'systems reply' and the 'robot reply'.

The systems reply concedes that in the imagined case Searle does not understand Chinese, but insists that the whole organized system consisting of Searle, the rule books, paper, pencil and room *does*. According to the systems reply the example errs in comparing Searle with the whole computer when in fact his role is analogous only to that of the central processing unit (CPU) of the computer, a small part of it, to which there is no need to attribute the understanding that is displayed by the entire system (see Semantics, conceptual role).

Searle offers a two-part response. First, he labels absurd the very suggestion that a system consisting of a person, some books, paper and a pencil could literally understand things or have a mind over and above that of the person alone. Such an ensemble he asserts is just the wrong sort of thing literally to understand or to have a mind. Second, he tries to avoid the objection by altering his example and removing himself from the room to a wide open field and committing all the rule books to memory. In such a case he would perform all the purely formal operations in his head, re-establishing his analogy with the whole computer. He asserts he would still not understand a word of Chinese (though some of his critics claim otherwise).

The robot reply concedes that the original Chinese room might not suffice for understanding Chinese. Since all its behaviour is strictly verbal, it is able to make connections between words and words, but not between words and the world: it might give coherent answers to questions about boiled eggs, but not have any ability to recognize an egg. The robot reply thus imagines a program installed within a robot that allows it to simulate the full range of human behaviour, verbal and non-verbal; and *that*, it is claimed, would count as understanding Chinese and having a mind.

Searle, however, disagrees. He notes that the robot's sensors would supply its internal processors only with more formal symbolic inputs. Were he and his Chinese room installed within the robot with additional rule books specifying how to respond to those additional symbols, and were these responses to drive the robot's apt behaviour, he, Searle, would still not understand a single word of Chinese. Nor, he argues, would the robot. Again,

the assumption that mentality requires consciousness seems in part to drive Searle's intuition. Critics less sympathetic to that assumption and more inclined to analyse intentionality in terms of causal interactive relations have been predictably more persuaded by the robot reply, especially if it is combined with the systems reply (see Semantics, informational).

Other objections to the Chinese room have sought to discredit it as a source of unreliable and misleading intuitions. Some have focused on the enormous disparity between the complexity and speed that would be required in a computer able to pass a Turing test, which the man in the room could not match. Others have stressed that strong AI need not be committed to the Turing test, and that the specific program by which behaviour is produced is crucial to whether something has a mind. In reply, Searle denies that speed or style of program is of any importance; what matters, he argues, is that the operations he performs are merely formal.

Chinul (1158-1210)

Chinul was the founder of the Korean Chogye school of Buddhism. He sought to reconcile the bifurcation between Kyo (doctrinal) thought and Sôn (Zen) practice that rent the Korean Buddhist tradition of his time, by showing the symbiotic connection between Buddhist philosophy and meditation. He also advocated a distinctive program of soteriology that became emblematic of Korean Buddhism from that time forward: an initial sudden awakening to the nature of the mind followed by gradual cultivation of that awakening until full enlightenment was achieved.

1 Life

Chinul, the National Master Puril Pojo, ordained as a monk when he was seven years old and passed the ecclesiastical examinations in the Sôn (Zen) branch of the Korean Buddhist tradition in 1182. According to his biography, however, Chinul became disillusioned with his colleagues' pursuit of worldly fame and profit, and soon afterwards decided to abandon ecclesiastical advancement for a contemplative life in the south of the Korean peninsula. Unlike many of his peers, Chinul did not make the incumbent pilgrimage to the mecca of the Chinese mainland and, despite his Sôn ecclesiastical affiliation, seems also not to have had close personal contacts with any teacher of meditation in Korea. A virtual autodidact, Chinul made up for this lack of individual instruction by drawing on sources that were readily available to him: the scriptures and scholastic commentaries of Kyo and the discourse records of previous masters of Sôn. His reading of scriptures and of Sôn texts catalyzed three separate awakenings, which led to his realization of the fundamental identity between Kyo and Sôn.

Chinul eventually established a number of monasteries and hermitages in the south of the Korean peninsula, including what became one of the three most important monasteries in the Korean Buddhist tradition, the Songgwang-sa (Piny Expanse Monastery). Chinul's works all date from this period of contemplation, starting with his earliest work, *Kwôn su Chônghye kyôlsa mun (Encouragement to Practice: The Compact of the Samādhi and Prajñā Community)*, written in 1190 upon the establishment of his first retreat society. *Susim kyôl (Secrets on Cultivating the Mind)*, arguably his most popular treatise, was composed between 1203 and 1205, and his *magnum opus*, *Pôpchip pyôrhaengnok chôryo pyôngip sagi (Excerpts from the Dharma Collection and Special Practice Record with Personal Notes)*, was completed in 1209, one year before his death. His remaining works were edited and published posthumously by his successor Chin'gak Hyesim (1178-1234).

The approach to Buddhism that Chinul outlined in his writings was marked by a strong reliance on correct doctrinal understanding at the inception of practice. Only after correct understanding had been forged regarding the justification and rationale of Buddhist practice would the student then go on to formal meditation training. That training could run the gamut from techniques heavily beholden to Kyo contemplative exercises, to the joint cultivation of concentration and wisdom (an approach deriving from one of the earliest stratum in Chinese Chan literature), to a new style of meditation just then developing on the Chinese mainland, the investigation of the 'critical phrase' (*kongan*; in Japanese, *kōan*). By synthesizing several antecedent strands of Buddhism, Chinul produced a uniquely Korean Buddhist school called Chogye (after the Korean pronunciation of Caogi Mountain, the monastic home of the sixth patriarch of the Chinese Chan school, Huineng (638-713)). Chinul's Chogye school became the dominant school of Korean Buddhism from the thirteenth century onward and Chinul's distinctive approach to Buddhist thought and practice became the model followed by most subsequent teachers within the Korean tradition (see Buddhist philosophy, Korean).

2 Buddhist ecumenicalism

Although Chinul was principally a Sôn meditator, he nevertheless retained a strong personal interest in the scriptural teachings of Kyo. Chinul's attempted reconciliation of the two branches of Buddhism sought to authenticate the Sôn approach in the scriptures of Kyo, thereby demonstrating the veracity of both. Chinul reviewed the entire Buddhist canon, seeking scriptural substantiation for the Sôn claim that enlightenment could be achieved solely through meditative introspection. While reading a text from the Flower Garland school, he finally found such substantiation and declared, 'What the Buddha said with his lips is Kyo; what the patriarchs of Sôn transmitted with their minds is Sôn. The mind and the words of the Buddha and patriarchs can certainly not be contradictory'. From that point on Chinul was convinced of the affinities between scriptural testimony and meditative experience, and his main ambition was to bring about a rapprochement between the Kyo and Sôn

strands of the Korean Buddhist tradition.

3 Introspection and the mind

For Chinul, the essential unity of Sôn and Kyo would be recognized once Buddhist adepts perceived their original natures: the quality of sentience that was most fundamental to all 'sentient' beings. Such insight was achieved through introspection, looking into the mind itself in order to verify the truth of one's innate buddhahood. It was through introspection - what Chinul termed 'tracing back the light of the mind' (*panjo*) or 'tracing the radiance emanating from the mind back to its source' (*hoegwang panjo*) - that students would overcome all limited conceptions about their true natures and perceive the vast web of interrelationships connecting themselves to all other things in the universe. This state of enlightenment achieved through Sôn practice was, Chinul claimed, what the Flower Garland school of Kyo called the unimpeded interpenetration between all phenomena.

Introspection was a technique that took the usual propulsion of the mind out into the world of the senses and turned it back in upon itself, until the mind's radiant source was discovered. To trace this inherent radiance of the mind back to its source meant to realize instantaneously that oneself was inherently enlightened, that one's mind was congenitally luminous. This brightness of mind was the faculty that illuminated sense objects, allowing them to be cognized. Hence, by tracing the radiance emanating from the mind back to its source, meditators discovered that core of luminosity that was fundamental to all sentient beings (see Illumination; Illuminationist philosophy). This discovery of their true nature constituted the initial understanding of the experience of enlightenment.

4 Soteriology

Chinul derived from this vision of the inherence of enlightenment a soteriological stratagem that came to be the hallmark of Korean Sôn: sudden awakening followed by gradual cultivation. This soteriological programme advocated that the optimal approach to Buddhist practice involved an initial understanding-awakening (*haeo*) to the true nature of the mind, which generated correct comprehension of both the absolute reality of all things (their nature) and their phenomenal appearances (their characteristics). This awakening, which occurred instantaneously, caused students to know that they were in fact innately enlightened and identical in principle with all the buddhas.

However, in Chinul's schema, simply knowing that one was enlightened was not sufficient to be able to act in an enlightened way. It was through a gradual process of subsequent spiritual cultivation that the understanding achieved through the initial awakening permeated all of one's behaviour, leading ultimately to realization-awakening (*chûngo*), or full enlightenment. The habitual patterns of thought and action developed during innumerable previous lifetimes were so deeply engrained that there was little hope of bringing them to an abrupt end; to change the inertial force of these habits required a long process of gradual cultivation. But, because students understood through the awakening that occurred at the very inception of practice that their minds were inherently pure and free of defilements, they could eliminate mental defilements while knowing that there was really nothing that needed to be eliminated. Similarly, students could also develop wholesome qualities of mind while realizing that there was nothing that needed to be developed. Chinul compared this interpretation of cultivation to the gradual calming of waves (mental defilements) after the wind that has whipped them up (the ignorance of one's innate buddhahood) had stopped: one was simply allowing a natural process to complete itself. Hence at the consummation of training one simply 'realized' in all facets of one's life the same truths that one had 'understood' initially. Chinul's soteriological stratagem of sudden awakening followed by gradual cultivation therefore accommodated a developmental component, while remaining strongly beholden to the subitist orientation that dominated much of Zen thought and practice throughout East Asia.

Chisholm, Roderick Milton (1916-)

Chisholm is an important analytic philosopher of the second half of the twentieth century. His work in epistemology, metaphysics and ethics is characterized by scrupulous attention to detail, the use of a few basic, undefined or primitive terms, and extraordinary clarity. One of the first Anglo-American philosophers to make fruitful use of Brentano and Meinong, Chisholm translated many of Brentano's philosophical writings. As one of the great teachers, Chisholm is widely known for the three editions of Theory of Knowledge, a short book and the standard text in US graduate epistemology courses. An ontological Platonist, Chisholm defends human free will and a strict sense of personal identity.

Roderick Milton Chisholm (born in North Attleboro, Massachusetts, USA) has come as close as any philosopher ever does to actually living the good life: marrying happily, teaching graduate philosophy at his Alma Mater and, in later years, living by the ocean. Upon completing an undergraduate philosophy major at Brown University, Chisholm entered the doctoral programme at Harvard, finishing in 1942. The subsequent three years of military experience, administering psychological tests to recruits, had little influence on his philosophy, nor did his brief stint at the Barnes Foundation lecturing on the philosophy of art. Chisholm returned to Brown in 1947 where he taught for the next forty years, heavily influencing Anglo-American epistemology and metaphysics.

Chisholm remained remarkably consistent throughout his career, opposing a variety of fashionable philosophical movements (phenomenalism, linguistic reductions of any sort and extensionalism) and simultaneously developing and elaborating original views on knowledge and justification, intentionality and ontology. In the early years he was most concerned to resist the dominant - and then popular - strains of positivism. For example, against phenomenalists who proposed to translate material-object statements into sensation statements, Chisholm convincingly argued that the requisite boundary or background conditions themselves could never be adequately stated using only sensation statements (see Phenomenalism §2).

It is easy to see in this pattern of reasoning the beginnings of his view, later known as 'the primacy of the intentional'. This doctrine would be elaborated in greater detail as Chisholm debated with Wilfrid Sellars and others who sought to reduce various human referential or intentional capacities to dispositions to engage in certain linguistic behaviour (see Intentionality §§1, 3). The central tenet of the primacy of the intentional is that the ability of humans to use language to refer to things in the world is to be explicated in terms of their ability to think of these same things. Sellars and others held the reverse.

Chisholm was inspired by the work of Franz Brentano to spend years searching for a mark or criterion of the mental. During this period he translated Brentano's *Wahrheit und Evidenz (The True and the Evident)* and many other works by Brentano and Meinong. He lectured frequently in Graz, Austria, winning in 1972 an honorary degree from the University, which was, according to him, the 'high spot' of his philosophical career.

Chisholm published three editions of his *Theory of Knowledge*. In all three, he was a pure foundationalist for a priori knowing, claiming that any a priori knowledge was either intuitively certain or known to be deducible from what was intuitively certain (see A priori §3). However, his account of empirical knowledge was a much more complicated story, containing a strong coherentist component. While claiming that certain internal mental states were 'self-presenting' and thus not in need of any evidential support, Chisholm consistently required substantial coherence among one's internal beliefs before one was justified in believing any proposition which went beyond the internal.

The foundational or anchoring self-presenting states and their corresponding beliefs consist of a variety of 'seemings'. What one seems to believe, seems to intend, seems to hope for or fear and, most importantly, seems to perceive, are all self-presenting; that is, if one is in any of these states and believes that one is in the state, then that belief is certain. Chisholm, following up a suggestion of his colleague Curt Ducasse, developed an adverbial theory of sensory experiencing. Chisholm urged that when referring to internal experiencing, we replace talk of 'sense-data' with adverbial expressions such as 'being appeared to redly'. In Chisholm's view, having the property of being appeared to redly was self-presenting and, thus, certain. The main advantage of this artificial way of speaking was the avoidance of ontological and epistemic puzzles about sense data. While 'being appeared to

redly' is somewhat comprehensible, the approach requires similar adverbs for all the other possible modes of sensing and suffers some implausibility because of their absence from ordinary language (see Mental states, adverbial theory of).

A fundamental characteristic of Chisholm's approach was to employ a fertile primitive term together with simple logical relationships to define other more complex concepts. For example, in the 3rd edition of *Theory of Knowledge* (1989b) the central foundational category of the 'certain' was defined in terms of the primitive comparative term 'more justified than' as follows:

p is certain for *S* =Df For every *q*, believing *p* is more justified for *S* than withholding *q*, and believing *p* is at least as justified for *S* as is believing *q*.

Definitions such as these occur throughout his work and it would not be inappropriate to label his approach 'Definitionalism'. Because of their clarity and simplicity, Chisholm's definitions generated numerous responses, mostly proposed counter-instances. Chisholm welcomed every example and never tired of modifying or 'chisholming away at' his definitions.

Chisholm handled epistemological scepticism by assuming that we have particular justified beliefs and the ability to examine them critically and thereby to discover principles of justification. These principles enabled Chisholm to construct a fifteen-category epistemic hierarchy, ranging from the certainly false to the certainly true. Each of the categories is defined in terms of the primitive 'more justified than'. Chisholm glosses this primitive in terms of an epistemic requirement to prefer. That is, when *S* is more justified in believing *p* than in believing *q*, *S* is required to prefer *p* to *q*. This epistemic requirement would then compete with all one's other kinds of requirement (including ethical), and from the competitive fray one's overall or real obligation would then emerge.

Chisholm was throughout his career inclined towards Platonism, always regarding attributes as abstract and eternal. The details of his ontology evolved and led him to seek a comprehensive theory of ontological categories. In *The First Person* (1981) Chisholm developed a theory of objective reference based around the primitive notion of 'direct attribution'. Direct attribution usually involves the 'emphatic reflexive' typified by such sentences as 'he believes that he himself is wise'. Chisholm uses his account of attribution to explain all *de re* or objective attributions.

Chisholm approached ethics theoretically, developing a theory of intrinsic value, and practically defending a kind of 'indeterminism'. The theory of intrinsic value employed undefined primitive terms to develop hierarchically arranged categories of both value and obligation. Chisholm's indeterminism, or theory of agent causation, affirmed free choices for which there were no internal or external conditions causally sufficient for that choice. Responsible agents themselves contribute the final condition which then brings about the actual choice and leads to the action.

List of works

A full bibliography can be found in Bogdan (1986).

Chisholm, R. (1957) *Perceiving: A Philosophical Study*, Ithaca, NY: Cornell University Press.(Exposition of the adverbial theory of perception, an account of adequate evidence based on an ethical primitive, and a Brentano-like view of intentionality. Carefully argued, yet accessible to the diligent beginning reader.)

Chisholm, R. (ed.) (1960) *Realism and the Background of Phenomenology*, Glencoe, IL: Free Press.(Collection of articles from 1870 to 1940 by German, British and American philosophers and psychologists concerned with the reality of objects of perception and thought. The editor's introduction is exceptionally useful and accessible, the articles themselves are of moderate complexity.)

Chisholm, R. (1966) *Theory of Knowledge*, Englewood Cliffs, NJ: Prentice Hall, 1st edn. (Closely argued exposition of entire epistemic system including a discussion of the metaphilosophical issues relevant to scepticism. Textbook for advanced students)

Chisholm, R. and Swartz, R. (eds) (1973) *Empirical Knowledge: Readings from Contemporary Sources*, Englewood Cliffs, NJ: Prentice Hall.(Collection of influential essays on scepticism, foundationalism, memory and belief. Most are accessible, but the essay by Sellars is difficult.)

Chisholm, R. (1976) *Person and Object: A Metaphysical Study*, La Salle, IL: Open Court.(Expanded version of the Carus Lectures on the self, agency, identity through time, and states of affairs; contains several appendices on justified belief and the part-whole relation. Readable but filled with definitions.)

Chisholm, R. (1977) *Theory of Knowledge*, Englewood Cliffs, NJ: Prentice Hall, 2nd edn. (Significantly revised and lengthened, with greater emphasis on the use of primitive terms to define complex concepts. Textbook for advanced students.)

Chisholm, R. and Haller, R. (eds) (1978) *Die Philosophie Franz Brentanos: Beiträge zur Brentano-Konferenz, Graz, 1977, (The philosophy of Franz Brentano: Papers from the Brentano conference, Graz, 1977)*, Amsterdam: Editions Rodopi N.V.(Contributions to the 1977 Conference on Brentano's philosophy in Graz, Austria.)

Chisholm, R. (1981) *The First Person: An Essay on Reference and Intentionality*, Minneapolis, MN: University of Minnesota Press.(Analysis of all reference, especially the referring capacity of linguistic expressions, in terms of first person reference. Concise and rather technical.)

Chisholm, R. (1982) *The Foundations of Knowing*, Minneapolis, MN: University of Minnesota Press.(Collection of previously published but slightly revised essays and an update of his epistemic system involving three new, short essays. Most parts are highly readable.)

Chisholm, R. (1986) *Brentano and Intrinsic Value*, New York: Cambridge University Press. (Exposition and interpretation of Brentano's theory of value, linking it to his general views on intentionality. Rather technical)

Chisholm, R. (1989a) *On Metaphysics*, Minneapolis, MN: University of Minnesota Press. (Collection of previously published, but revised, essays on action, identity, reference, and ontology; almost all views expressed here are worked out in greater detail elsewhere. Readable.)

Chisholm, R. (1989b) *Theory of Knowledge*, Englewood Cliffs, NJ: Prentice Hall, 3rd edn. (Substantially revised and shortened, with several chapters devoted to the metaphilosophical issues raised by the internalism-externalism and foundationalism-coherentism debates. Textbook for advanced students.)

Chisholm, R. (1996) *A Realistic Theory of Categories: An Essay on Ontology*, New York: Cambridge University Press.(An extremely concise reduction of all ontological entities using eight undefined categorial locutions. Includes all major metaphysical doctrines and central epistemological views, few real-world examples and many technical formulations. For advanced readers only.)

Akademische Druck- und Verlagsanstalt, 8 vols.(All the books and essays that Meinong published, together with his intellectual self-portrait and major reviews. Volumes 4 and 5 are edited by Chisholm. Volume 7 contains a comprehensive index. The supplementary volume contains a selection of posthumous material including lecture notes, notes on other philosophers' writings, and a lexicon of logic and epistemology.)

Chomsky, Noam (1928-)

Fish swim, birds fly, people talk. The talents displayed by fish and birds rest on specific biological structures whose intricate detail is attributable to genetic endowment. Human linguistic capacity similarly rests on dedicated mental structures many of whose specific details are an innate biological endowment of the species. One of Chomsky's central concerns has been to press this analogy and uncover its implications for theories of mind, meaning and knowledge.

This work has proceeded along two broad fronts.

First, Chomsky has fundamentally restructured grammatical research. Due to his work, the central object of study in linguistics is 'the language faculty', a postulated mental organ which is dedicated to acquiring linguistic knowledge and is involved in various aspects of language-use, including the production and understanding of utterances. The aim of linguistic theory is to describe the initial state of this faculty and how it changes with exposure to linguistic data. Chomsky (1981) characterizes the initial state of the language faculty as a set of principles and parameters. Language acquisition consists in setting these open parameter values on the basis of linguistic data available to a child. The initial state of the system is a Universal Grammar (UG): a super-recipe for concocting language-specific grammars. Grammars constitute the knowledge of particular languages that result when parametric values are fixed.

Linguistic theory, given these views, has a double mission. First, it aims to 'adequately' characterize the grammars (and hence the mental states) attained by native speakers. Theories are 'descriptively adequate' if they attain this goal. In addition, linguistic theory aims to explain how grammatical competence is attained. Theories are 'explanatorily adequate' if they show how descriptively adequate grammars can arise on the basis of exposure to 'primary linguistic data' (PLD): the data children are exposed to and use in attaining their native grammars. Explanatory adequacy rests on an articulated theory of UG, and in particular a detailed theory of the general principles and open parameters that characterize the initial state of the language faculty (that is, the biologically endowed mental structures).

Chomsky has also pursued a second set of concerns. He has vigorously criticized many philosophical nostrums from the perspective of this revitalized approach to linguistics. Three topics he has consistently returned to are:

- *Knowledge of language and its general epistemological implications*
- *Indeterminacy and underdetermination in linguistic theory*
- *Person-specific 'I-languages' versus socially constituted 'E-languages' as the proper objects of scientific study.*

1 The aims and principles of linguistic theory

There is an intimate relation between how a problem is conceived and the kinds of explanations one should offer. Chomsky proposes that we identify explanation in linguistics with a solution to the problem of how children can attain mastery of their native languages on the basis of a rather slender database. This is often referred to as 'the logical problem of language acquisition'.

A natural language assigns meanings to an unbounded number of sentences. Humans typically come to master at least one such language in a surprisingly short time, without conscious effort, explicit instruction or apparent difficulty. How is this possible? There are significant constraints on any acceptable answer.

First, a human can acquire any language if placed in the appropriate speech community. Grow up in Boston and one grows up speaking English the way Bostonians do. However, the 'primary linguistic data' (PLD) available to the child are unable to guide the task unaided. There are four kinds of problems with the data that prevent it from shaping the outcome:

(a) The set of sentences the child is exposed to is finite. However, the knowledge attained extends over an unbounded domain of sentences.
(b) The child is exposed not to sentences but to utterances of sentences. These are imperfect vehicles for the transmission of sentential information as they can be defective in various ways. Slurred speech, half sentences, slips of the tongue and mispronunciations are only a few of the ways that utterances can obscure sentence

structure.
(c) Acquisition takes place without explicit guidance by the speech community. This is so for a variety of reasons. Children do not make many errors to begin with when one considers the range of logically possible mistakes. Moreover, adults do not engage in systematic corrections of errors that do occur and even when correction is offered children seem neither to notice nor to care. At any rate, children seem surprisingly immune to any form of adult linguistic intrusion (see Lightfoot 1982).
(d) Last of all, and most importantly, of the linguistic evidence theoretically available to the child, it is likely that only simple sentences are absorbed. The gap between input and intake is attributable to various cognitive limitations such as short attention span and limited memory. This implies that the acquisition process is primarily guided by the information available in well-formed simple sentences. Negative data (the information available in unacceptable ill-formed sentences) and complex data (the information yielded by complex constructions) are not among the PLD that guide the process of grammar acquisition. The child constructing its native grammar is limited to an informationally restricted subset of the relevant data. In contrast to the evidence that the linguist exploits in theory construction, the information the child uses in building its grammar is severely restricted. This suggests that whenever the linguistic properties of complex clauses diverge from simple ones, the acquisition of this knowledge cannot be driven by data. Induction is insufficient as the relevant information is simply unavailable in the PLD.

The general picture that emerges from these considerations is that attaining linguistic competence involves the acquisition of a grammar, and that humans come equipped with a rich innate system that guides the process of grammar construction. This system is supple enough to allow for the acquisition of any natural language grammar, yet rigid enough to guide the process despite the degeneracy and deficiency of the PLD. Linguistic theorizing takes the above facts as boundary conditions and aims both at descriptive adequacy (that is, to characterize the knowledge that speakers have of their native grammars) and explanatory adequacy (that is, to adumbrate the fine structure of the innate capacity) (see Language, innateness of).

Issues of descriptive and explanatory adequacy have loomed large in Chomsky's work since the beginning. Chomsky's objection, for example, to 'Markov models' of human linguistic competence was that they were incapable of dealing with long distance dependencies exemplified by conditional constructions in English and hence could not be descriptively adequate. His argument in favour of a transformational approach to grammar rested on the claim that it allowed for the statement of crucial generalizations evident in the judgments of native speakers and so advanced the goal of descriptive adequacy (Chomsky 1957). Similarly, his influential critique (1959) of Skinner's *Verbal Behavior* consisted in showing that the learning theory presented therein was explanatorily inadequate. It was either too vague to be of scientific value or clearly incorrect given even moderately precise notions of stimulus or reinforcement.

The shift from the early *Syntactic Structures* (1957) theory to the one in *Aspects of a Theory of Syntax* (1965) was also motivated by concerns of explanatory adequacy. In the earlier model the recursive application of transformations allows for the generation of more and more complex sentences from the sentences produced by the 'phrase structure' component of the grammar. In the *Aspects* theory, recursion is incorporated into the phrase structure component itself, and removed from the transformational part of the theory (see Syntax §3). The impetus for this was the observation that greater explanatory adequacy could be attained by grammars that had a level of 'Deep Structure' incorporating a recursive base component. In particular, Fillmore (1963) observed that the various optional transformations in a *Syntactic Structures* theory always applied in a particular order in any given derivation. This order is unexplained in a *Syntactic Structures* theory; in *Aspects* it is deduced. Thus, the move to an Aspects-style grammar is motivated on grounds of greater explanatory adequacy: introducing Deep Structure and moving recursion to the base allows for a more restricted theory of Universal Grammar. All things being equal, restricting UG is always desirable as it advances a central goal of grammatical theory; the more restricted the options innately available for grammar construction, the easier it is to explain how language acquisition is possible, despite the difficulties in the PLD noted above.

The same logic motivates various later additions to and shifts in grammatical theory. For example, a major move in the 1970s was radically to simplify transformational operations so as to make their acquisition easier. This involves eliminating any mention of construction-specific properties from transformational rules. For example, an *Aspects* rule for passive constructions looks like (1), the left-hand side being the Structural Description (SD) and the right hand side being the Structural Change (SC):

to X-NP1-V-NP2-Y→ $(1)\mathrm{X}-\mathrm{NP2}-\mathrm{be}+\mathrm{en}\ \mathrm{V}-\mathrm{by}+\mathrm{NP1}-\mathrm{Y}\mathrm{x}$

This rule would explain, for instance the grammaticality of ‘the ball is kicked by John’ given that of ‘John kicks the ball’. Observe that the SC involves the constants ‘ $\mathrm{be}+\mathrm{en}$’ and ‘by’. The SD mentions three general expressions, ‘NP1’, ‘V’ and ‘NP2’ and treats these as part of the context for the application of the rule. In place of this, Chomsky proposed eliminating the passive rule and replacing it with a more general rule that moves NPs (Chomsky 1977, 1986). The passive rule in (1) involves two applications of the ‘Move NP’ rule, one moving the subject ‘NP1’ to the ‘by’ phrase, and another moving the object ‘NP2’ to the subject position. In effect, all the elements that make the passive rule in (1) specific to transitive constructions are deleted and a simpler rule (‘Move NP’) replaces it.

There is a potential empirical cost to simple rules, however. The simpler a transformation the more it generates unacceptable outputs. Thus, while a grammar with (1) would not derive ‘was jumped by John’ from ‘John jumped’, a grammar eschewing (1) and opting for the simpler ‘Move NP’ rule is not similarly restricted. To prevent overgeneration, therefore, the structure of UG must be enriched with general grammatical conditions that function to reign in the undesired overgeneration (Chomsky 1973, 1977, 1986). Chomsky has repeatedly emphasized the tension inherent in developing theories with both wide empirical coverage and reasonable levels of explanatory adequacy.

A high point of this research agenda is Chomsky’s *Lectures on Government and Binding* (1981). Here the transformational component is reduced to the extremely simple rule ‘Move *a*’ - that is, move anything anywhere. To ensure that this transformational liberty does not result in generative chaos, various additions to the grammar are incorporated, many conditions on grammatical operations and outputs are proposed, and many earlier proposals (by both Chomsky and others) are refined. Among these are trace theory, the binding theory, bounding theory, case theory, theta theory and the Empty Category Principle. The picture of the grammar that Chomsky’s *Lectures* presents is that of a highly modular series of interacting subsystems which in concert restrict the operation of very general and very simple grammatical rules. In contrast to earlier traditional approaches to grammar, *Lectures* witnesses the virtual elimination of grammatical constructions as theoretical constructs. Thus, in Government Binding (GB)-style theories there are no rules of Passive, Raising, Relativization or Question Formation as there were in earlier theories. Within GB, language variation is not a matter of different grammars having different rules. Rather, the phenomena attested in different languages are deduced by variously setting the parameters of Universal Grammar. Given the interaction of the grammatical modules, a few parametric changes can result in what appear on the surface to be very different linguistic configurations. In contrast to earlier approaches to language, variation consists not in employing different kinds of rules, but in having set the parameters of an otherwise fixed system in somewhat different ways (see Chomsky 1983).

The GB research programme has proven to be quite successful in both its descriptive range and its explanatory appeal. Despite this, Chomsky has urged a yet more ambitious avenue of research. He has embarked on the development of a rationalist approach to grammar that goes under the name of ‘Minimalism’ (Chomsky 1995). The theory is ‘rationalist’ both in that it is grounded on very simple and perspicuous first principles, and in that it makes use only of notions required by ‘virtual conceptual necessity’. Chomsky hopes to make do with concepts that no approach to grammar can conceivably do without and remain true to the most obvious features of linguistic competence. For example, every theory of grammar treats sentences as pairings of sounds and meanings. Thus, any theory will require that every sentence have a phonological and an interpretative structure. In GB theories, these sorts of information are encoded in the PF (Phonetic Form) and LF (Logical Form) phrase markers respectively. In addition, GB theories recognize two other distinctive grammatical levels: S-structure and D-structure. A minimal theory, Chomsky argues, should dispense with everything but LF and PF. It will be based on natural ‘economy’ principles and indispensable primitives. Chomsky has suggested reanalysing many of the restrictions that GB theories impose in terms of ‘least effort’ notions such as ‘shortest move’ and ‘last resort movement’. For example, he proposes that the unacceptability of sentences such as ‘John is expected will win’, are ultimately due to the fact that the moved NP ‘John’ need not have moved from the embedded subject position (between ‘expected’ and ‘will’) as it fulfils no grammatical requirement by so moving. This work is still in its infancy, but it has already prompted significant revisions of earlier conclusions. For example, with the elimination of D-structure, the recursive engine of the grammar has once again become the province of generalized transformations. Whatever its

ultimate success, however, Minimalism continues the pursuit of the broad goals of descriptive and explanatory adequacy enunciated in Chomsky's earliest work.

2 Knowledge of language

According to Chomsky, the three fundamental epistemological questions in the domain of language are 'What constitutes knowledge of language?', 'How is knowledge of language acquired?' and 'How is this knowledge put to use?'. The answer to the first question is given by a particular generative grammar. Harold's knowledge of English is identified with Harold's being in a particular mental/brain state. A descriptively adequate grammar characterizes this part of Harold's mental/brain make-up. An answer to the second question is provided by a specification of UG and the principles that take the initial state of the language faculty to the knowledgeable state on exposure to PLD. Harold knows English in virtue of being genetically endowed with a language faculty and having been normally brought up in an English-speaking community. Beyond this, further issues of grounding are unnecessary. Issues of epistemological justification and grounding in the data are replaced by questions concerning the fine structure of the initial state of the language faculty and how its open parameters are set on the basis of PLD. The third question is answered by outlining how linguistic knowledge interacts with other cognitive capacities and abilities to issue in various linguistic acts such as expressing one's thoughts, parsing incoming speech and so on (see Chomsky 1986).

How much does the language case tell us about epistemological issues in other domains? In other words, should knowledge of quantum mechanics be analysed in a similar vein, that is, being in a particular mental state, grounded in specific innate capacities and so on. Chomsky only makes sparse comments on this general issue, but those he advances suggest that he believes that knowledge in these domains should be approached in much the same way they are approached in the domain of language. This suggests that humans have an innate science-forming capacity that underlies our success in the few domains of inquiry in which there has indeed been scientific success. As in the domain of language, this capacity is focused and modular rather than being a general all-purpose tool and this, Chomsky speculates, might well underlie the patchiness of our successes. Where we have the right biological propensities, we develop rich insightful theories that far outpace the data from which they are projected. Where this mind/brain structure is lacking, mysteries abound that seem recalcitrant to systematic inquiry. Stressing our cognitive limits is a staple of Chomsky's general epistemological reflections. If humans are part of the natural world we should expect there to be problems that fall within our cognitive grasp and mysteries that lie outside it. The rich theoretical insights allowed in the natural sciences are the result of a chance convergence between properties of the natural world and properties of the human mind/brain (see Chomsky 1975).

3 Indeterminacy and underdetermination

Knowledge of language, Chomsky has argued, presents a strong argument in favour of traditional rationalist approaches to mind and against traditional empiricist approaches (see Learning §1; Rationalism). In particular, 'learning' is treated as more akin to growth and the course of acquisition is seen more as the unfolding of innate propensities under the trigger of experiential input than as the result of the shaping effects of the environment. This rationalist perspective is now quite common and this is largely due to Chomsky's efforts. Chomsky has consistently warned against empiricist prejudices in philosophy, and in no instance more strongly than in his critique of Quine's methodological remarks on linguistics (for example, see Quine 1960).

Chomsky takes Quine to be arguing that linguistic investigations are beset with problems greater than those endemic to inquiry in general. Whereas empirical investigation in general suffers from underdetermination of theory by evidence, linguistic study is beset with the added problem of indeterminacy (see Radical translation and radical interpretation §§2-3). Indeterminacy differs from standard inductive underdetermination (see Underdetermination) in that where there is indeterminacy 'there is no real question of right choice' among competing proposals. Chomsky interprets Quine as arguing that 'determining truth in the study of language differs from the problem of determining truth in the study of physics' (Chomsky 1975: 182-3).

In reply, Chomsky (1969) argues that Quine's thesis rests on classical empiricist assumptions about how languages are acquired. Quine, he argues, supposes that humans have 'an innate quality space with a built-in distance measure' tuned to certain 'simple physical correlates'. In addition, certain kinds of induction in this space are permitted. Beyond this, however, 'language-learning is a matter of association of sentences to one another and to

certain stimuli through conditioning'. Further, one cannot 'make significant generalizations about language or common-sense theories, and the child has no concept of language or of "common-sense" prior to this training' (Chomsky 1969: 54-5, 63).

Chomsky notes that Quine provides no evidence to support these assumptions. Nor can there be any good evidence to support them if the nature of the learning problem in the domain of language is characterized as Chomsky has argued it must be. Chomsky concludes that 'Quine's thesis of the indeterminacy of translation amounts to an implausible and quite unsubstantiated empirical claim about what the mind brings to the problem of acquisition of language (or of knowledge in general) as an innate property' (Chomsky 1969: 66). Stripped of these tendentious empirical assumptions, Quine fails to show that indeterminacy is anything other than the familiar problem of underdetermination of theory by evidence as applied to linguistics. Chomsky (1996) has since argued that the ultimate source of many critiques of the mental sciences in general and linguistics in particular (including Quine's indeterminacy thesis) is a kind of methodological dualism that takes humans to be separate from the natural world. This dualism is manifest in the a priori constraints that philosophers place on explanations in the mental sciences, which would be regarded as inappropriate if applied to the physical sciences.

In this vein Chomsky asks, for example, why access to consciousness is so often taken to be crucial in substantiating the claim that humans have I-language or follow rules. Suppose, he asks, we had a theory that perfectly described what happens when sound waves hit the ear, stimulating the performance system to access the cognitive system and construct a logical form that interacts with other cognitive systems to yield comprehension, in so far as the language faculty enters into this process. What more could be desired? The insistence that this entire process be accessible to consciousness in order for the account to be credible, he argues, is a demand beyond naturalism, a form of methodological dualism of dubious standing that would be summarily rejected if raised elsewhere.

Or consider the oft-voiced suspicions concerning mentalist approaches in psychology. Many philosophers are ready to accept these as perhaps temporarily necessary but ultimately, the view seems to be, mentalist theories must reduce to physical ones to be truly legitimate. Chomsky argues that this sentiment is another manifestation of methodological dualism and should be rejected. First, it presupposes that there is a tenable distinction between the mental and the physical. However, Chomsky argues that since Newton undermined the Cartesian theory of body by showing that more 'occult' forces were required in an adequate physics, mind-body dualism has lost all grounding. Second, even if reduction were possible, reduction comes in many varieties and there is little reason to believe that the contours of the reducing physical theory would be left unaffected by the process. Since Newton, Chomsky notes, 'physical' has been an honorific term that signifies those areas in which we have some nontrivial degree of theoretical understanding. The relevant scientific question is whether some theory or other offers interesting descriptions and explanations. The further insistence that its primitives be couched in physical vocabulary is either vacuous (because 'physical' has no general connotation) or illegitimate (another instance of methodological dualism).

The general conclusion Chomsky draws is that whatever problems linguistic theory encounters, it is no more methodologically problematic than theories in other domains. He attributes the qualms of philosophers to lingering empiricist dogma or an indefensible epistemological dualism.

4 I-language versus E-language

Given the aims of Chomskian linguistic theory, the proper objects of study are the I-languages internalized by native speakers, rather than public E(xternal)-languages used by populations. Chomsky denies that public E-languages are interesting objects of scientific study. Indeed he denies that E-languages can be coherently specified as they simply do not exist. The proper objects of inquiry are I-languages; 'I' standing for intensional, internal and individual. An I-language is individual in that each speaker has one. This focus turns the common wisdom on its head. E-languages like English, Swahili and so forth are (at best) radical idealizations for Chomsky, or (at worst) incoherent pseudo-objects. At best, E-languages are the intersection of the common properties of various I-languages. Thus, for example, it is not that speakers communicate because they have a language in common; rather wherever I-languages *overlap* communication is possible.

An I-language is internal in the sense of being part of a speaker's individual mental make-up. It is neither a

Platonic object nor a social construct. Also, an I-language is intensional, not extensional. Comprised as it is of an unbounded number of sentences, a language cannot be 'given' except via a specification of the function that generates them, that is a grammar for that language. Thus, it is languages in intension, languages dressed in all of their grammatical robes, not simple concatenations of words, that are the proper objects of scientific interest. One consequence of this is that weak generative capacity (that is, the extensional equivalence of languages generated by different grammars) is of dubious interest. In short, the shift from E-language to I-language turns many long-standing questions around, raising some to prominence that were considered secondary and relegating many that previously were considered crucial to the status of pseudo-questions.

Many philosophers have found Chomsky's focus on I-language problematic. To illustrate, we will consider an important philosophical critique and Chomsky's reply.

Dummett (1986) argues against internalist approaches to language that they fail to provide an account of notions like 'language of a community' or 'community norms' in the sense presupposed by virtually all work in the philosophy of language and philosophical semantics. These notions, Dummett claims, are required to provide a notion of a common public language which 'exists independently of any particular speakers' and of which native speakers have a 'partial, and partially erroneous, grasp' (see Language, social nature of §2).

The naturalistic study of language, Chomsky counters, has no place for a Platonistic notion of language, a notion of language outside the mind/brain that is common to various speakers and to which each speaker stands in some cognitive relation. The reason is that this Platonistic reification rests on notions like 'language' and 'community' that are hopelessly under-specified. Asking if two people speak the same language is, in Chomsky's opinion, to ask a highly context-dependent question - much like asking whether Boston is near New York. What counts as a community depends on shifting expectations of individuals and groups. Human society is not neatly divided into communities with languages and their norms. Thus, what counts as a community is too under-specified to be useful for theoretical purposes. Therefore, it is not a defect of linguistic theory that these notions play no role within it.

From Chomsky's perspective E-languages are epiphenomenal objects, if coherent at all. I-language in its universal aspects is part of the human genotype and specifies one aspect of the human mind/brain. Under the triggering effects of experience a particular grammar arises in the mind/brain of an individual. From this perspective, universal grammar and the steady-state grammars that arise from them are real objects. They will be physically realized in the genetic code and the adult brain. E-language, in contrast, has a murky ontological status. Chomsky (1980) argues that the priority of I-language cannot be reasonably doubted once we observe that languages involve an infinite pairing of sounds and meanings. Given that language is infinite, it cannot be specified except in so far as some finite characterization - a function in intension - is provided. It might be possible to give some characterization to the notion 'a language used by a population' but only indirectly via a grammatical specification of the language. But this concedes the priority of I-language as the claim unpacks into something like: each person in the relevant population has a grammar in their mind/brain that determines the E-language. Thus, at best, an E-language is that object which the I-language specifies. However, even this might be giving too much reality to E-languages, for there is nothing in the notion I-language that requires that what they specify corresponds to languages as commonly construed, that is, things like French, English and so on. It is consistent with Chomsky's viewpoint that I-language never specifies any object that we might pre-theoretically call a language. Whether this is indeed the case, the key point is to realize that the move from grammar to language is a step away from real mechanisms to objects of a higher degree of abstraction. I-language is epistemologically and ontologically hardier than E-language, much philosophical opinion to the contrary.

Christine de Pizan (1365-*c.*1430)

Christine de Pizan, France's 'first woman of letters', is primarily remembered as a courtly poet and a propagandist for women. Her extensive writings were influenced by the early humanists, reflecting an interest in education (particularly for women and young people) and in government. Following Aquinas, Christine defined wisdom as the highest intellectual virtue and tried to apply the concept of the just war to contemporary problems. Her works are also noteworthy for their contribution to the transmission of Italian literature to Parisian intellectual circles.

Christine de Pizan was born in Venice. Her father and grandfather, city officials in Venice and graduates of the University of Bologna, would undoubtedly have known Petrarch (see Petrarca, F.), and possibly Boccaccio. Christine's father, an astrologer and medical man of some reputation, was invited to the French court of the cultivated King Charles V, and Christine grew up as part of Charles' entourage. Her father encouraged Christine's early taste for study, and she probably received a basic education alongside her two brothers until her marriage, at the age of fifteen, to Etienne Castel, a young notary who was soon appointed a royal secretary. Widowed at twenty-five, with her father already dead, Christine found herself in desperate financial straits with three children to support. However, she managed to obtain patronage through her taste for study and subsequently for writing. Her attachment to early humanistic interests can be attributed to her programme of self-education during these early years of widowhood, as well as to her father's early influence and possibly to his library.

A debate with young Parisian intellectuals, in which Christine insisted on the superiority of Dante's work over Jean de Meun's *Roman de la Rose (Romance of the Rose)*, strengthened her reputation. Becoming successful as a court poet, Christine was one of the first scholars to introduce Dante to France, using him in her first long work, *L'Epître d'Othéa à Hector (The Letter of Othea to Hector)* (*c.*1400) and her semi-autobiographical poem *Le Chemin de Long Estude (The Long Road of Study)* (*c.*1403). Her *Livre de la Cité des Dames (Book of the City of Ladies)* (1405) was inspired in large measure by Boccaccio's *De Claris Mulieribus (Concerning Outstanding Women)*, and to a lesser degree by his *Decameron*, retelling selected tales from a woman's point of view. In addition, the influence of Boccaccio's concept of poetry (as expressed in his *De Genealogia Deorum Gentilium (A Genealogy of Gentile Gods)*) can be discerned in her *Letter of Othea*. Her debt to Petrarch is more elusive, although she mentions him in *The City of Ladies* and reworks his version of the Griselda story there.

Her long allegorical poem *La Mutacion de Fortune (The Mutation of Fortune)* (1403) led to a commission from the duke of Burgundy to write a biography of his late brother, *Les Fais et Bonnes Meurs du Sage Roy Charles V (The Deeds and Good Customs of the Wise King Charles V)*. In this work she did not just give a historical account of Charles' life, but portrayed him as an exemplary ruler and a philosopher, a model of the philosopher-king. Drawing inspiration from Aquinas' commentary on Aristotle's *Metaphysics* she proposed a definition of wisdom as the highest intellectual virtue and the philosophical life as the prerogative of the free individual.

In common with other early humanists, Christine shows particular interest in the education of the young, notably the French dauphin, Louis de Guyenne. She wrote *Le Livre du Corps de Policie (The Book of the Body Politic)* (*c.*1406) and *Le Livre de la Paix (The Book of Peace)* (1413) for Louis, and her *Les Fais d'Armes et de Chevalerie (Deeds of Arms and of Chivalry)* (1410) was probably intended to form part of his military education. Inspired by the Roman author Vegetius as well as by contemporary needs, *Les Fais d'Armes* was the first professional military treatise to have appeared in some time. The first chapters comprise a significant discussion of the concept of the just war, with Christine attempting to apply traditional ideas to the problems of her own time. The book subsequently played a role in the reform of the French army in the second half of the fifteenth century. Her *Livre des Trois Vertus (Book of Three Virtues)* (1405), devoted to the education of women and dedicated to the dauphin's wife, Marguerite of Burgundy, was also significant: it was reprinted as late as 1536, and influenced European leaders including Margaret of Austria, Anne of France and Louise of Savoy.

Chrysippus (*c*.280-*c*.206 BC)

The Greek philosopher Chrysippus of Soli was the third and greatest head of the Stoic school in Athens. He wrote voluminously, and in particular developed Stoic logic into a truly formidable system. His philosophy is effectively identical with 'early Stoicism'.

Chrysippus was born at Soli in Cilicia (southern Turkey). He came to Athens to study philosophy, initially with the Academic sceptic Arcesilaus. By the time he transferred his allegiance to the Stoic school, its founder Zeno of Citium was dead and had been succeeded by Cleanthes, who became Chrysippus' teacher. For a while he taught philosophy outside the Stoa, but in 232 BC Cleanthes died and Chrysippus succeeded him, holding the office till his own death.

Chrysippus may well have been relatively poor. In his work *On Livelihoods* he tackled the question of how a philosopher might appropriately earn a living. The only three acceptable means, he concluded, were serving a king (if one could not oneself be a king), reliance on friends, and teaching. There is no evidence that Chrysippus, like some other Stoics, adopted the first of these practices.

From the long excerpts of his writings which have survived in other authors, it seems that his Greek was clumsy and often obscure. (The people of his native Soli were so notorious for their poor Greek as to have given the 'solecism' its name.) Nevertheless, he wrote prolifically, his works totalling at least 705 rolls of papyrus, and what he wrote was widely read. Often he returned to the same topic several times in different treatises. His writings were also accused of beng padded out with endless quotations. Not all were doctrinal expositions - some were investigative and open-ended.

'If there had been no Chryippus', it was said, 'there would have been no Stoa'. Chrysippus is generally regarded as the person who built the full Stoic system. (The entry Stoicism is therefore in effect an account of his philosophy.) Whether Chrysippean Stoicism should be, as it often is, called 'orthodox' Stoicism is less clear. Later Stoics did not treat him as altogether authoritative: some, including his successor Antipater as well as Posidonius, were openly critical of him. On the other hand, his writings became and remained the classic Stoic texts to cite and analyse. Exegesis of passages from Chrysippus was a later Stoic teaching method, for example in the school of Epictetus, and conversely his writings were the primary target of anti-Stoic polemicists such as Plutarch and Galen. But Chrysippus presented Zeno rather than himself as the voice of authority, and many of his ideas were developed as defences and interpretations of Zeno's pronouncements, often against the rival interpretations of Cleanthes and others.

Chrysippus contributed extensively to every area of Stoic thought, with the possible exception of epistemology. Above all, he was the school's master logician, and the list of his writings partially preserved by Diogenes Laertius includes an astonishing 118 titles of logical treatises. They include at least seven works, filling fifteen rolls, on the Liar Paradox alone.

Church, Alonzo (1903-95)

Alonzo Church was one of the twentieth century's leading logicians. His work covers an extensive range of topics in logic and in other areas of mathematics. His most influential work relates to three areas: the general properties of functions, as presented in his 'calculus of lambda conversion'; the theory of computability and the decision problem, to which he made fundamental contributions, known as Church's thesis and Church's theorem; and intensional logic, developing Frege's theory of sense and denotation. In the last four decades of his life Church continued working mostly in this last area.

1 Life

Alonzo Church was born in Washington, DC. After receiving his Ph.D. from Princeton in 1927 he spent two years as a National Research Fellow at Harvard, Göttingen and Amsterdam. He then held positions in mathematics and philosophy at Princeton (1929-67) and UCLA (1967-90).

Church's work covers an extensive range of topics in mathematics and logic, including the Lorentz transformation, differentials, recursive arithmetic, postulate theory, the law of the excluded middle, non-standard interpretations of propositional logic, higher-order logic, a theory of weak implication and notes on the history of logic. His most influential work, however, relates to three areas: (1) the general properties of functions, in his 'calculus of lambda conversion' (see Lambda calculus), first presented in 1932 and developed in 1941; (2) effective calculability - his influential proposal that the effectively calculable functions can be identified with the recursive functions (see Church's thesis) and his negative solution to the decision problem ('*Entscheidungsproblem*') for predicate logic (see Church's theorem and the decision problem) were first published in 1936; and (3) intensional logic and a development of Frege's theory of sense and denotation (see Church 1951; Frege, G. §3). In the last four decades of his life Church continued working mostly in this last area. Particularly important is his series of papers on its 'revised' formulations (1973, 1974, 1993).

While at Princeton Church became one of the principal founders of the *Journal of Symbolic Logic*, the first volume of which appeared in 1936. He was an editor of the journal for its first forty-four volumes.

2 A theory of functions

The notion of mathematical function dominated Church's early work. He concentrated only on the general properties of functions 'independently of their appearance in any particular mathematical (or other) domain'. In his explanation of the notion of function, Church diverged from the standard view in mathematics and logic. Of importance is his emphasis on the intensional aspect of functions according to which they are not identified with a set of ordered tuples as is usual in mathematics, but are regarded as *operations* - items which are applied to tuples of objects (their arguments) to yield other single objects as values. The general properties of functions were studied in his λ-calculus, which presented a language permitting unambiguous denotation of functions. The principal expression of this language is an abstraction operator which is used to construct an expression for a function from an expression for an arbitrary value. For example, '$\lambda x.x^2$' denotes the function which takes any number to its square. The rules of transformation (conversion) of the calculus provide a guide for derivations among expressions of the above type.

The λ-calculus has had a significant effect on the development of logic. It was shown that the original formulation of the calculus is equivalent to the combinatory logic of Schönfinkel and, for this reason, Church is considered to be one of the founders of combinatory logic. The λ-calculus also played an important role in the development of intensional logic, particularly in that part of it which takes intensions as functions of a certain type.

A study of general properties of functions led Church to two seminal discoveries concerning the problem of whether it is possible to make all of mathematics algorithmic. The first of these was his conjecture concerning a precise demarcation of the class of functions characterized intuitively as algorithmically or effectively computable. This conjecture, which has come to be known as 'Church's thesis', is that this intuitively characterized class of functions is identical with the precisely characterized class of functions known as general recursive (see Computability theory §2). The second is Church's proof that the so-called 'decision problem' is unsolvable. The general decision problem for mathematics asks whether for every class of mathematical problems there is an

algorithm which decides the answer. More particularly, the decision problem for predicate logic asks whether there is an algorithm for deciding logical truth. Church established a negative answer to both questions (see Church's theorem and the decision problem).

3 The logic of sense and denotation

Church's work on functions is partly responsible for his interest in developing a theory of intensions. His λ-calculus utilizes a notion of 'function-in-intension' (as opposed to 'function-in-extension') and he notes that two functions-in-intension *f* and *g* might be different - might, that is, differ in intension or 'meaning' - even if they share the same domain of arguments and for each *n*-tuple of objects $a_1, \ldots, a_n$ of that domain, $f(a_1, \ldots, a_n) = g(a_1, \ldots, a_n)$. In his earlier work, the notion of difference in meaning was left unexplained. The last four decades, however, he devoted to developing a theory of this difference in meaning. The result was his 'logic of sense and denotation', based on Frege's theory of proper names (see Proper names §1; Frege, G. §§2-3). Church follows Frege in assigning two sorts of semantic values to proper names. A proper name is said to *express* its 'sense' and to *name* its 'denotation' (or 'reference'). Frege and Church are of the view that two names having the same denotation might none the less differ in sense.

Another characteristic feature of the Frege-Church theory is that declarative sentences are treated as names. They express their senses (propositions), and denote (or name) their truth-values.

Like Frege, Church also distinguished between two uses of proper names: the ordinary and the oblique. The principal criterion for obliqueness is the failure of substitutivity for equality ($=$), and for material equivalence ($\equiv$). Examples include contexts with modalities (possibility or necessity) and sentences expressing belief or knowledge ('propositional attitudes'). Church states that in oblique contexts a proper name does not have its 'usual' denotation but rather denotes what in ordinary contexts is its sense.

Church also accepted the following Fregean views concerning the role played by names in determining the sense and denotation of their larger contexts: if a name is replaced by another having the same sense, the sense of the whole context remains unchanged; and if a name is replaced by another having the same denotation, the denotation of the whole context remains unchanged.

In spite of these similarities between Church and Frege, there are also significant differences. For example, to avoid antinomies found in Frege's theory by Russell, Church built his logic of sense and denotation on a theory of types (see Theory of types). Also, unlike Frege's informal treatment, Church's was formal. Using this method, he formulated exact criteria of identity for 'concepts' or senses and identified three alternative forms for the theory, depending upon the particular criterion of identity adopted.

One of these (known as 'Alternative (2)') is designed to treat oblique contexts with modalities but is ill-suited for contexts expressing knowledge and belief, for which purpose the so-called 'Alternative (0)' was developed.

Powerful arguments against any Fregean theory of proper names were presented by Kripke and others. Nevertheless, many aspects of his theory can still be salvaged and it retains a strong appeal as a theory of propositional attitudes. Church offered compelling arguments that attitudes such as belief are relations between agents and propositions rather than between agents and sentences. Further, Alternative (0) offers a sufficiently fine-grained notion of proposition, by use of which Church was able to resolve a number of philosophical and logical puzzles relating to propositional attitudes, for example, those relating to the failure of substitutivity of coreferential expressions in propositional attitudes (see Sense and reference §§4-5), the paradox of analysis and Mates' puzzle concerning iterated epistemic operators. Church's analysis of intensions for expressions other than proper names is also suggestive - particularly those parts of it that pertain to his Fregean theory of definite descriptions (including his criticisms of Russell's theory of such descriptions).

List of works

Church, A. (1999, forthcoming) *Collected Papers*, ed. T. Burge, H.B. Enderton and M. Zeleny, Cambridge, MA: MIT Press.(A new two-volume collection of Church's work.)

Church, A. (1932, 1933) ‘A Set of Postulates for the Foundation of Logic’, papers 1 and 2, *Annals of Mathematics* 33: 346-66, 34: 839-64.(Church’s first published formulation of the calculus of lambda-conversion.)

Church, A. (1936a) ‘An Unsolvable Problem of Elementary Number Theory’, *American Journal of Mathematics* 58: 345-63.(A seminal paper of mathematical logic; the first publication of Church’s thesis and Church’s theorem.)

Church, A. (1936b) ‘A Note on the *Entscheidungsproblem*’, and correction, *Journal of Symbolic Logic* 1: 40-1, 101-2.(Church’s theorem applied to the classical predicate calculus to show that it is undecidable.)

Church, A. (1940) ‘A Formulation of the Simple Theory of Types’, *Journal of Symbolic Logic* 5: 56-68. (Includes a version of the calculus of lambda-conversion based on the simple theory of types (which played a major role in his logic of sense and denotation).)

Church, A. (1941) *The Calculi of Lambda-Conversion*, Princeton, NJ: Princeton University Press.(Classic source for the calculus of lambda-conversion.)

Church, A. (1943) ‘Carnap’s *Introduction to Semantics*’, *The Philosophical Review* 52: 298-304. (A review in which Church suggests and ‘proves’ the thesis that the denotation of a declarative sentence is a truth-value.)

Church, A. (1950) ‘On Carnap’s Analysis of Statements of Assertion and Belief’, *Analysis* 10: 97-9.(A classic paper in logical semantics and the philosophy of language; develops Langford’s test of translation and shows that verbs such as ‘believes’, ‘knows’, ‘says’ cannot be treated as expressing relations between agents and sentences but rather as expressing relations between agents and propositions.)

Church, A. (1951) ‘A Formulation of the Logic of Sense and Denotation’, in *Structure, Method and Meaning: Essays in Honor of Henry M. Sheffer*, New York: Liberal Arts Press, 3-24.(Classic source but requires considerable training in formal logic.)

Church, A. (1954) ‘Intensional Isomorphism and Identity of Belief’, *Philosophical Studies* 5: 65-73. (Informal presentation of Church’s notion of synonymous isomorphism; forms a foundation for his Alternative (0).)

Church, A. (1956) *Introduction to Mathematical Logic*, vol. 1, Princeton, NJ: Princeton University Press.(An excellent introduction to mathematical logic. The introduction provides a clear, extensive and informal exposition of Church’s views on the theory of sense and denotation; helpful for those interested in Church’s logistic treatment of intensions.)

Church, A. (1960) ‘Logic and Analysis’, in *Atti del XII Congresso Internazionale di Filosofia*, Florence, 77-81.(A relatively ‘unknown’ paper that presents Church’s views on the relation of logic to philosophy and of the place of logic in analysis of epistemic matters.)

Church, A. (1973, 1974) ‘Outline of a Revised Formulation of the Logic of Sense and Denotation’, parts 1 and 2, *Noûs* 7: 24-33, 8: 135-56.(Incorporates the notion of possible world.)

Church, A. (1974) ‘Russellian Simple Type Theory’, *Proceedings and Addresses of the American Philosophical Association* 47: 21-33. (A re-formulation of Russell’s mathematical logic in terms of a simple theory of types. Church argues that if the re-formulation is to be presented as intensional logic then Frege’s distinction between sense and denotation will have to be introduced.)

Church, A. (1976) ‘Comparison of Russell’s Resolution of the Semantical Antinomies with that of Tarski’, *Journal of Symbolic Logic* 41: 747-60.(Two resolutions of the semantic antinomies are compared: Russell’s based on a ramified theory of types and Tarski’s based on the object-language/metalanguage distinction. Church shows that the former resolution is a special case of the latter.)

Church, A. (1993) ‘A Revised Formulation of the Logic of Sense and Denotation. Alternative (1)’, *Noûs* 27: 141-57. (Presents a system of logical axioms characterizing propositions that might be taken as objects of assertion and belief. The system is based on a simple theory of types and it is shown that it is set-theoretically consistent. Requires a considerable training in formal logic.)

Church's theorem and the decision problem

Church's theorem, published in 1936, states that the set of valid formulas of first-order logic is not effectively decidable: there is no method or algorithm for deciding which formulas of first-order logic are valid. Church's paper exhibited an undecidable combinatorial problem $\mathcal{P}$ and showed that $\mathcal{P}$ was representable in first-order logic. If first-order logic were decidable, $\mathcal{P}$ would also be decidable. Since $\mathcal{P}$ is undecidable, first-order logic must also be undecidable.

*Church's theorem is a negative solution to the decision problem (*Entscheidungsproblem*), the problem of finding a method for deciding whether a given formula of first-order logic is valid, or satisfiable, or neither. The great contribution of Church (and, independently, Turing) was not merely to prove that there is no method but also to propose a mathematical definition of the notion of 'effectively solvable problem', that is, a problem solvable by means of a method or algorithm.*

The period 1929-37 was very eventful for logic. It began with Gödel's proof that first-order logic is semantically complete, that is, that the set of provable formulas coincides with the set of logically valid formulas. It included the incompleteness theorems of Gödel (see Gödel's theorems §§3-4), Church's theorem showing the undecidability of first-order logic, and the statement by Church and Alan Turing of Church's thesis equating the intuitive notion of effectiveness and the mathematical notion of recursiveness. The paper by Turing, which exhibited a universal Turing machine and introduced the notion of a computer program, was the culmination of the period.

Church's theorem, published in 1936 (see Davis 1965), states that the set of valid formulas of first-order logic is not effectively decidable: there is no method or algorithm for deciding which formulas of first-order logic are valid. Turing's slightly later paper proved the same result in a slightly different way. Both papers followed the same pattern. They exhibited an undecidable combinatorial problem $\mathcal{P}$ and showed that $\mathcal{P}$ was representable in first-order logic. If first-order logic were decidable, $\mathcal{P}$ would also be decidable. Since $\mathcal{P}$ is undecidable, first-order logic must also be undecidable.

Hilbert and Ackermann had formulated the *Entscheidungsproblem* (the decision problem) as the problem of finding a method for deciding whether a given formula of first-order logic is valid, or satisfiable, or neither; that is, whether all, some, or none of its possible interpretations are true. Church's theorem is a negative solution to the *Entscheidungsproblem*.

Hilbert and Ackermann had not proposed a mathematical definition of what constitutes a method, and the great contribution of Church and Turing was not merely to prove that there is no method but also to propose a mathematical definition of the notion of 'effectively solvable problem', that is, a problem solvable by means of a method or algorithm.

The technical result proved by Church only showed that the set of *provable* formulas of first-order logic is not λ-definable, that is, not definable in the λ-calculus, a logical calculus invented by Church (see Lambda calculus). To conclude that the set of *valid* formulas in first-order logic is not 'effectively' decidable, we need two additional facts. We need to equate validity in first-order logic with provability in a particular formal system, a result proved already by Gödel, but about which Church had some qualms due to the non-constructive nature of the proof. We also need to equate the mathematical notion of λ-definability (or the provably equivalent notions of recursiveness and Turing computability) with the *intuitive* notion of effective computability. This second equality is Church's thesis (see Church's thesis). Assuming Church's thesis, Church's theorem constitutes a negative solution to the problem of giving a uniform procedure for deciding which formulas of first-order logic are valid.

The particular version of first-order logic which Church used to prove his theorem included, as part of the language, the equality symbol, a constant and several function symbols. However, such a rich vocabulary is not actually necessary. Even first-order logic with a single dyadic predicate symbol is undecidable. (This is in sharp contrast to the decidability of the special case where the language consists solely of monadic predicates, a result first proved by Löwenheim (1915).)

Also, despite Church's qualms about the non-constructiveness of Gödel's completeness proof, Church's theorem is

rather sturdy. It is known that, for Gödel's completeness result to hold, one must allow formulas with non-recursive models to be considered to be satisfiable. However, even if one restricts the possible models - for example, if one confines oneself to finite models or to constructive (recursive) models - the set of valid formulas remains non-recursive, and Church's theorem remains true, although first-order logic is no longer complete relative to these restricted classes of models.

Hilbert's *Entscheidungsproblem* as formulated by Hilbert and Ackermann inquired about the decision problem for logic as such. This would also include second-order logic, whose undecidability follows of course from that of the (weaker) first-order logic. But here a slightly more complex situation prevails. First-order logic, while not decidable, is none the less semi-decidable in that we do have a procedure to enumerate the set of all valid formulas. What prevents first-order logic from being decidable is that we do not have a procedure to enumerate the complementary set of all formulas which are *not* valid, that is, of all formulas whose negations are satisfiable (have at least one true interpretation). However, second-order logic is not even semi-decidable, a fact which is already implicit in Gödel's incompleteness result for arithmetic, and which pre-dated Church's theorem by about five years (see Gödel's theorems §1). Thus, at the time that Church proved his theorem, only the question for first-order logic was really open.

Note that a positive solution to the *Entscheidungsproblem* would not have required a mathematical definition of effectiveness. It would have sufficed to present a method for deciding which formulas of first-order logic were valid and to rely on our mathematical intuition to see that the method qualified as a genuine algorithm. However, a negative solution requires us to delimit the notion of effective computability to show that validity in first-order logic lies outside it, and such a delimitation necessarily requires that the notion of effectiveness be given a mathematical definition, or at least be mathematically circumscribed.

Church himself did not provide in his paper an independent definition of the intuitive notion of effectiveness. Rather he proposed that his technical notion, λ-definability, be taken to be a definition of the intuitive notion of effectiveness. A more substantial analysis was provided by Alan Turing in his paper (see Davis 1965). Turing analysed the possible mental algorithms that a human being could carry out and claimed that his machines, Turing machines, could also carry them out. A crucial element in Turing's argument was the claim that a human computer (sic) would only be able to carry out algorithms which utilized a finite number of distinct symbols, and that while he was carrying out an algorithm, his mind could only occupy a finite number of distinct states. Turing's argument for the first claim is that if the process of calculation used infinitely many basic symbols, then some of these symbols would be very close to others and confusion could not be avoided. He remarks that the same also holds of states of mind, but offers no argument. (See Turing machines.) Gödel, in fact, describes Turing's remarks in this context as a 'philosophical error'. If we do accept Turing's justification that effectiveness equals Turing computability, then since λ-definability and Turing computability are provably equivalent, Turing's analysis also provides substantial ammunition for Church's own claim.

Church's thesis

An algorithm or mechanical procedure A is said to 'compute' a function f if, for any n in the domain of f, when given n as input, A eventually produces fn as output. A function is 'computable' if there is an algorithm that computes it. A set S is 'decidable' if there is an algorithm that decides membership in S: if, given any appropriate n as input, the algorithm would output 'yes' if $n \in S$, and 'no' if $n \notin S$. The notions of 'algorithm', 'computable' and 'decidable' are informal (or pre-formal) in that they have meaning independently of, and prior to, attempts at rigorous formulation.

Church's thesis, first proposed by Alonzo Church in a paper published in 1936, is the assertion that a function is computable if and only if it is recursive: 'We now define the notion…of an effectively calculable function…by identifying it with the notion of a recursive function….' Independently, Alan Turing argued that a function is computable if and only if there is a Turing machine that computes it; and he showed that a function is Turing-computable if and only if it is recursive.

Church's thesis is widely accepted today. Since an algorithm can be 'read off' a recursive derivation, every recursive function is computable. Three types of 'evidence' have been cited for the converse. First, every algorithm that has been examined has been shown to compute a recursive function. Second, Turing, Church and others provided analyses of the moves available to a person following a mechanical procedure, arguing that everything can be simulated by a Turing machine, a recursive derivation, and so on. The third consideration is 'confluence'. Several different characterizations, developed more or less independently, have been shown to be coextensive, suggesting that all of them are on target. The list includes recursiveness, Turing computability, Herbrand-Gödel derivability, λ-definability and Markov algorithm computability.

1 Computability and decidability

The algorithms or mechanical procedures envisaged here must determine what is to be done at each step, involving no creativity or intuition on the part of the agent (other than an ability to recognize symbols). The paradigm is a recipe for routine calculation, or a computer program.

An algorithm (or mechanical procedure) *A* 'computes' a function *f* if, for any *n* in the domain of *f*, when given *n* as input, *A* produces *fn* as output. A function is 'computable' if there is an algorithm that computes it. (See Computability theory §2.) There is no fixed limit on the amount of materials or memory required for a computation, nor on the number of steps an algorithm might take. If a function were computed only by an algorithm whose execution required more memory than there are particles in the solar system, it would not be capable of computation in any realistic sense, yet it would still be computable. What is required is that the algorithm have only finitely many steps. A set *S* is 'decidable' if there is an algorithm that 'decides' membership in *S*: if, given any appropriate *n* as input, the algorithm outputs 'yes' if $n \in S$, and 'no' if $n \notin S$.

Strictly speaking, computability should apply only to functions on things like marks on paper and magnetic media, since these are the items that can be manipulated by computers and algorithms. It is common to take computability to apply to functions on 'strings', which are the abstract forms of sequences of characters. For example, the string '$abc23$' is the form of all actual and possible concrete inscriptions of these three letters and two numerals. It is also common to think of computability as applying to functions on natural numbers, via canonical notation.

The root meaning of 'computability' would be something like 'capable of computation', and the root meaning of 'decidability', something like 'capable of decision'. Thus, these are modal notions. Computability is also an 'extensional' notion: it applies to functions themselves, not to descriptions or presentations of functions. Moreover, the quantifier 'there is an algorithm' does not involve (*de re*) knowledge of an algorithm (see De re/de dicto §1). For example, let $fn = 1$ if there is a string of at least *n* consecutive 5's in the decimal expansion of π, and $fn = 0$ otherwise. No one knows of any algorithm *A* such that *A* computes *f*. Nevertheless, the function *f* is computable. If there are indefinitely long strings of consecutive 5's in the expansion of π, then *f* is computed by an algorithm that produces '1' no matter the input. Otherwise, let *N* be the longest string of consecutive 5's in the expansion. Then *f* is computed by an algorithm that outputs '1' for all inputs less than or equal to *N*, and outputs '0' for all other inputs. In all cases, then, *f* is computable.

The notions of recursiveness (see Computability theory §1) and λ-definability (see Lambda calculus §4) arose as part of various foundational programmes earlier in the twentieth century. Church and his students became interested in the extension of the λ-definable functions. They set themselves the task of investigating various (computable) functions, to see if they could be shown to be λ-definable. Shortly after Kleene proved that the predecessor function is λ-definable, Church proposed his thesis: that a function is computable if and only if it is recursive. He published it after Kleene established the connection with recursiveness.

Although algorithms have been constructed since antiquity, it is curious that no one attempted a precise characterization of computability *per se* before the mid-1930s, at which time a number of more or less independent characterizations appeared almost simultaneously. One motivation was the desire, or need, to establish *negative* results about computability and decidability. Notice that the straightforward way to show that a given function is computable is to give an algorithm. This does not require a rigorous definition of computability, since most theorists can recognize an algorithm when they see one. To establish that a given function is *not* computable, on the other hand, one needs to show that *no* algorithm computes the function. This requires the formulation of a property shared by all algorithms or all computable functions. The straightforward route to such a property is a careful characterization of computability. At the time, the construction of algorithms for various purposes was a central item on the agenda of mathematical logic (see Hilbert's programme and formalism). Virtually all of the original characterizations of computability include theorems that certain functions are not computable or that certain sets are not decidable.

A related motivation was the desire to understand the extent of Gödel's incompleteness theorem. The original proof only applied to a particular system, but it is clear that the proof could be generalized to any common axiomatization of arithmetic. This, and the work on Hilbert's programme, led to the problem of characterizing just what a formal deductive system is. One requirement is that the syntax should be 'effective', in the sense that the collections of well-formed formulas, axioms and rules of inference should all be decidable. The natural generalization of the incompleteness theorem is that there is no sufficiently rich, effective and complete deductive system for arithmetic. As above, to establish this generalization, one needs a grasp of the limits of algorithms, and this came with the characterization of computability (see Gödel's theorems; Formal languages and systems).

The modern notion of a function as an arbitrary correspondence between sets has emerged only towards the end of the twentieth century. In the past, the very idea of a 'non-computable' function might have been questioned, as it is today by constructivists and intuitionists. It might be added that from the constructivist perspective, Church's thesis has a sharp formulation. For a constructivist, a formula of the form $\forall x \exists ! y \Phi(x, y)$ states that, given any *x*, *one can find* a unique *y* such that $\Phi(x, y)$ holds. This amounts to an assertion that a certain function is computable. Thus, Church's thesis is the scheme that if $\forall x \exists ! y \Phi(x, y)$ then there is a *recursive* function *f* such that $\forall x \Phi(x, fx)$. In other words, for a constructivist, Church's thesis is a claim that *all* number-theoretic functions are recursive. Among intuitionists and constructivists, Church's thesis is controversial (see Intuitionism; Constructivism in mathematics; Beeson 1985; McCarty 1987).

As noted, however, there is a consensus among (non-constructivist) mathematicians and logicians that Church's thesis is correct. Within recursive function theory, a technique has been developed, sometimes called 'argument by Church's thesis', wherein one concludes that a function is recursive, or that a set is decidable, just because there is an algorithm for it. For example, for each natural number *n*, let $g(n)$ be the sum of the divisors of *n*. Since it is routine to give an algorithm to factor a number and add its divisors, one can conclude, by Church's thesis, that *g* is recursive. One does not have to deal with the details of recursive derivations, Turing machines and so on. By avoiding tedious detail, the perspective is broadened, leading to greater insight (see Rogers 1967).

2 What is Church's thesis?

Despite the consensus on the correctness of Church's thesis, there is not much agreement over what the correctness amounts to. What does Church's thesis mean? Does it have a determinate truth-value? Can it be known and, if so, how?

Computability is a pragmatic, pre-theoretic property of functions. It relates somehow to human abilities, suitably idealized. As such, Church's thesis is an important case study for the philosophical problem of accounting for the relationship between mathematics and material or human reality. Some authors have gone so far as to call

computability a 'psychological' concept, since it relates to competence in grasping and executing procedures. One of the founders of computability, Emil Post, wrote that

> for full generality a complete analysis would have to be made of all the possible ways in which the human mind could set up finite processes…we have to do with a certain activity of the human mind as situated in the universe. As activity, this logico-mathematical process has certain temporal properties; as situated in the universe it has certain spatial properties.
>
> (Davis 1965: 408-19)

This passage also notes the aforementioned modal nature of computability. Notice, however, that recursiveness, Turing computability, λ-definability and so on are at least *prima facie* non-modal. They are defined in terms of quantifiers ranging over abstract entities, such as natural numbers, strings on a finite alphabet and so on. Thus, Church's thesis identifies the extension of an idealized, pragmatic, modal property of functions with the extension of a formal, rigorously defined, *prima facie* non-modal arithmetic property. On the surface, then, Church's thesis proposes an exchange of modality for ontology. How are such proposals to be evaluated?

A closely related matter concerns vagueness. Typically, pragmatic, modal notions do not have sharp boundaries. There are, for example, borderline cases of 'climbable mountains', 'liftable weights' and 'teachable students'. Clearly, there are also borderline cases of functions 'capable of computation', if we do not idealize. Slogans such as 'ignoring limits on memory and materials' sharpen the notion, but it is still not clear that idealized computability, as defined above, is an unequivocal property with *completely* precise boundaries. Recursiveness and Turing computability, on the other hand, do appear to have precise boundaries. *Prima facie*, then, Church's thesis identifies a vague notion with a precise one.

Clearly, a vague property cannot *exactly* coincide with a precise one. So, if computability is in fact vague, Church's thesis does not literally have a determinate truth-value or else it is false. Church's thesis might then be thought of as a proposal that recursiveness be *substituted* for computability, for certain purposes. It would be similar to a pronouncement such as 'For the purposes of this form, a resident is defined to be…'.

The value of 'definitions' or 'precisifications' of vague terms depends on the purposes at hand. Given the extensive idealizations, Church's thesis seems best suited for establishing *negative* results about computability. If one shows, for example, that a function is not recursive, that is conclusive reason to hold that it is not 'capable of computation': one should give up trying to compute it. Suppose, on the other hand, that a function has been shown to be recursive. By itself, this gives no information on the feasibility of an algorithm, and thus it does not establish that the function can be calculated, in any realistic sense. Moreover, it is of little value to anyone interested in actually computing the function. For this purpose, there are other, less idealized models, such as 'finite state' computability, 'push down' computability, primitive recursiveness and computability in polynomial time or space (see Complexity, computational).

A different interpretation of Church's thesis is that even though computability is a pre-theoretic notion, it is nevertheless a precise, mathematical property of functions. One might hold, for example, that there are determinate mathematical structures underlying idealized human abilities to calculate, write programs, or even think. Understood this way, Church's thesis states that this property is coextensive with another precise mathematical notion, recursiveness. Thus, Church's thesis has a truth-value. The 'arguments from confluence' support this interpretation. The fact that a number of *prima facie* different attempts to characterize computability lead to the same extension suggests that recursiveness, Turing computability and so on delimit the boundaries of a 'natural kind' underlying computation.

3 Epistemic status

The Goldbach conjecture (that every even number greater than 4 is the sum of two primes) and the 'twin prime' conjecture (that there are infinitely many numbers *n* such that *n* and $n+2$ are both prime) are long-standing open problems in number theory. They can be settled, if at all, by mathematical proof. It is widely held that Church's thesis is not like this. Its evidence is not mathematical. Because of the connection with human abilities, and perhaps because of the supposed vagueness, Church's thesis has been called an 'empirical' or 'quasi-empirical' matter.

As noted above, one type of evidence cited for Church’s thesis is that every algorithm that has been investigated has been shown to compute a recursive function. This is consonant with the quasi-empirical nature of Church’s thesis (on a certain view of scientific hypotheses). The intuitive ability to recognize algorithms is analogous to ‘observation’, and showing that an algorithm computes a recursive function amounts to ‘confirmation’ of Church’s thesis (see Confirmation theory). This type of evidence was prominent in the thought of Church and Kleene.

Some theorists, on the other hand, do regard Church’s thesis as a mathematical matter, capable of whatever epistemic standards are applicable there, and some regard the thesis as proved. Robin Gandy (1988), for example, suggests that Turing’s direct argument that every algorithm can be simulated on a Turing machine does not merely provide evidence for an inductive, scientific hypothesis; rather, it ‘proves a theorem’. Turing provides a careful analysis of a human executing an algorithm, showing how each ‘step’ can be simulated on a Turing machine. There are lemmas that the number of symbols and the number of ‘states of mind’ must be finite. Gandy regards the analysis to be as convincing as typical mathematical work. Apparently, Gödel was also convinced by Turing’s arguments, and not by the ‘quasi-empirical’ evidence (see Davis 1982).

On these views, the pragmatic nature of computability, and its potential vagueness, do not automatically disqualify Church’s thesis from mathematics. This is consistent with a widely held position that there is no sharp boundary between mathematics and empirical science (see Duhem, P.M.M.; Quine, W.V.O.). Mathematics has its roots in everyday life, and cannot be severed from it. Even a cursory look at the history of the notions underlying recursiveness reveals ambivalence, ambiguity and vagueness, especially in the notion of ‘set’ (see Mendelson 1990). Yet no one doubts that sets and recursive functions belong to mathematics. According to the view at hand, computability is no different.

4 Other theses

There are similar ‘theses’ in the history of mathematics and science. Consideration of these may shed some light on the philosophical issues here.

The notion of a grammatical sentence of a natural language is clearly pragmatic, modal and at least *prima facie* vague. This is contrasted with formal, mathematical characterizations of grammaticality, as proposed by linguists. Unlike Church’s thesis, however, there is no consensus on one of these grammars.

Closer to home, the notion of ‘validity’, or ‘logical consequence’, is *prima facie* pragmatic and modal, if not vague. In typical logic textbooks, validity is related to inference abilities, and an argument is said to be valid if it is not possible for the premises to be true and the conclusion false. Yet, when one reads on, validity is formally defined in terms of models, which are mathematical constructions on sets. Thus, we have another exchange of modality and ontology. The identification of the pre-formal validity with model-theoretic consequence may be called ‘Tarski’s thesis’. Notice that there is a consideration of confluence here. Gödel’s completeness theorem shows that for first-order languages, the model-theoretic notion of consequence coincides in extension with a deductive one (see Consequence, conceptions of; Model theory; Proof theory).

Within more traditional mathematics, consider notions such as ‘area’, ‘volume’ and ‘continuity’. While these do not appear pragmatic and modal, they did have clear meanings before their rigorous formulations in analysis and measure theory. Moreover, the notions do have uses in everyday and scientific life and there seem to be borderline cases of the pre-theoretic notions. In modern mathematics, however, these notions all have rigorous, precise definitions. The various identifications with the pre-theoretic notions may be called Euclid’s thesis, Lebesgue’s thesis, Weierstrass’ thesis, Cauchy’s thesis, and so on. The reader may decide the extent to which these theses have determinate truth-values, whether they are mathematical or ‘quasi-empirical’, and whether they have been (or can be) established with characteristic mathematical rigour.

Chông Yagyong (Tasan) (1762-1836)

Chông Yagyong was a government official and a scholar of the Sirhak (Practical Learning) school in the late Chosôn dynasty of Korea. He is also known by his literary name Tasan. A man of independent mind, Chông was not satisfied with the conventional interpretation of the Confucian classics. He immersed himself in research on the Six Classics and the Four Books, investigating a whole range of writings by scholars from the Han through the Qing dynasties and searching for the true and original intents of the ancient sages uncorrupted by later interpretations. In the course of clarifying ancient terms and concepts, he frequently challenged the orthodox views of the Song neo-Confucianism that had largely dominated the intellectual climate of Chosôn Korea. Although he frequently praised Zhu Xi, he did not hesitate to point out the shortcomings of the neo-Confucian masters.

In his youth, Chông Yagyong came under the influence of the scholarship of Yi Ik (1681-1763). In 1784 he was first introduced to the teachings of Catholicism by his friend Yi Pyôk (1754-86), who provided him with a copy of Matteo Ricci's *The True Meaning of Our Lord in Heaven*, and thereafter he was exposed to Catholicism and Western learning. Having passed the higher civil examination in 1789, he held various government posts, such as local magistrate, Secret Inspector, Third Minister and Royal Secretary. Because of his association with Catholicism his official career was not smooth, but he nevertheless became one of the favorites of King Chôngjo who, recognizing his brilliance, protected him as much as possible. In 1801, during the persecution of Catholics, Chông was forced out of office and had to spend the next eighteen years in exile. His earlier renunciation of Catholicism may have saved him from certain death, and there are conflicting accounts as to whether his public disclaimer was genuine. While in exile, Chông devoted his energy to scholarship, mostly writing commentaries on the classics. In 1818 he was released from exile and allowed to return to his home at Mahyôn, an eastern suburb of present-day Seoul, where he lived until his death. He wrote extensively on a wide range of subjects, but he is better known for his scholarly commentaries on the Six Classics and the Four Books, and his three studies on government and economy.

Not satisfied with the neo-Confucian cosmology based on principle (*i*; in Chinese, *li*) and material force (*ki*; in Chinese, *qi*), Chông developed his own concept of heaven (see Qi; Tian). He sees heaven or the heavenly ruler as a monotheistic spirit who created the universe and presides over all beings. Unlike plants or animals, every person is endowed by heaven with its spiritual quality, enabling them to transcend all things. At the same time, people are equipped with dual qualities: the autonomy to choose good or evil and the natural inclination 'to take pleasure in the good and to be ashamed of evil'. Chông then explains that the reason why 'the superior man does not wait till he sees things, to be cautious' is because he is aware of the presence of the heavenly ruler even in a dark room. Thus men have the obligation to obey and respect heaven, from whence emanates all ethical and moral value. One can see the influence of Catholicism in Chông's concept of heaven, and similarly in his studies of the Six Classics and the Four Books, he built up his own system of philosophy through an eclectic approach.

Chông also valued practical applications of knowledge, and thus declared that 'the teaching of the School of the Principle is to know the Way through self-awareness so that one can exert his utmost toward realizing the right principle'. Of the many works on government and economy that he wrote, three are best known: *Kyôngse yup'yo(Designs for Good Government)*, *Mongmin simsô (Admonitions on Governing the People)* and *Hûmhûm sinsô (Towards a New Jurisprudence)*. Not unlike John Locke, Chông believed that the first governments were formed when people in a community agreed to let a judicious man settle a dispute that arose. Accordingly, he maintained that government exists on behalf of the people. In place of the chaotic land system that prevailed in Korea at the time, he proposed a 'village land' (*yôjôn*) system whereby land would be owned and cultivated jointly by village members and the harvest distributed according to the amount of work contributed by each individual. His overriding goal for the government was to promote and protect the well-being of the people as a whole. A man of practical mind, he also devised cranes that were used in the construction of the fortifications at Suwôn, set up a pontoon bridge over the Han River and experimented with smallpox and measles inoculations. A versatile scholar, he wrote on a wide range of subjects including history, geography, philology and military science. He is regarded as the greatest of all the Sirhak scholars who stood between the traditional and the modern periods in Korea.

Cicero, Marcus Tullius (106-43 BC)

Cicero, pre-eminent Roman statesman and orator of the first century BC and a prolific writer, composed the first substantial body of philosophical work in Latin. Rising from small-town obscurity to the pinnacle of Rome's staunchly conservative aristocracy, he devoted most of his life to public affairs. But he was deeply interested in philosophy throughout his life, and during two intervals of forced withdrawal from politics wrote two series of dialogues, first elaborating his political ideals and later examining central issues in epistemology, ethics and theology. Designed to establish philosophical study as an integral part of Roman culture, these works are heavily indebted to Greek philosophy, and some of the later dialogues are largely summaries of Hellenistic debates. But Cicero reworked his sources substantially, and his methodical expositions are thoughtful, judicious and, on questions of politics and morals, often creative. An adherent of the sceptical New Academy, he was opposed to dogmatism but ready to accept the most cogent arguments on topics important to him. His vigorously argued and eloquent critical discussions of perennial problems greatly enriched the intellectual and moral heritage of Rome and shaped Western traditions of liberal education, republican government and rationalism in religion and ethics. These works also afford invaluable insight into the course of philosophy during the three centuries after Aristotle.

1 Life and writings

Marcus Tullius Cicero, elder son of a locally influential family in the town of Arpinum, moved to Rome in his youth to pursue a career in law and government. There he studied with several Greek philosophers, including the Academic Philo of Larissa, and after a brilliant legal debut he spent two years in Greece studying philosophy and rhetoric with Antiochus and the Stoic Posidonius. Upon his return he won election to a major office that brought lifelong membership of the Senate (Rome's supreme governing body) and soon established himself as the foremost advocate of the age. Elected consul (Rome's chief executive office) in 63 BC, he suppressed an insurrection and was hailed his country's saviour. But opponents contrived his exile in 58 BC, and when he returned the following year, he found his influence severely diminished. Turning to writing, he formulated and defended his political ideals in three pioneering dialogues (see §2). When Julius Caesar precipitated civil war in 49 BC, Cicero sided reluctantly with the opposition as the lesser threat to Roman institutions. Caesar's swift victory brought dictatorship, and Cicero, although granted clemency, was excluded from politics. Returning to writing, he championed free political discussion in a series of rhetorical works, then composed in twenty months a dozen works (nine survive whole or in large part) discussing central problems in Hellenistic philosophy (see §§3-4) (see Hellenistic philosophy). The political turmoil that followed Caesar's assassination in March 44 BC slowed, then halted this astonishing pace as he rallied resistance to Mark Antony's despotic designs. His campaign might well have succeeded had Antony not colluded with Caesar's adoptive heir, the future Augustus: Cicero was assassinated and his head impaled in the Forum where he had spoken so often and so eloquently.

Cicero's extant works, although only part of his enormous output, comprise over fifty speeches, nearly a thousand letters to friends and associates, several works on rhetorical theory and practice, and twelve on philosophical topics. This vast corpus, besides displaying great intellectual range and stylistic virtuosity, embodies Cicero's conviction that philosophy and rhetoric are interdependent and both essential for the improvement of human life and society. His oratory bears the stamp of his theoretical studies, and his treatises and dialogues are richly oratorical. The philosophical works in particular unite the rhetorical techniques and ample style of Roman oratory with the analytical methods and conceptual apparatus of Greek philosophy in a unique fusion of eloquence and insight. All but one of these works are fictional dialogues. Some portray Cicero or eminent Romans of the previous century discoursing at length among friends; others, employing a format that reflects Roman political and legal practice but also the critical spirit Cicero admired in Plato and his sceptical heirs in the New Academy (see §3), present paired speeches for and against Epicurean and Stoic theories. Composed for audiences unused to abstract theory and systematic analysis, the discussions lapse at times into earnest declamation, and the close questioning found in Plato's dialogues is rare. However, they are methodically organized and often incisive, and by presenting opposing views and arguments in clear and engaging terms, they dramatize the significance of fundamental problems and encourage critical reflection.

2 Classical republicanism

Cicero’s first philosophical works are three long dialogues that analyse and evaluate the political institutions and practices of contemporary Rome in the light of Greek theory. Although largely conservative, they provided the first political theory in Latin and remain the most systematic ancient account of Roman government; while others described events, only Cicero advanced a structural analysis. Written when Rome’s republican traditions were collapsing under unprecedented concentrations of economic and military power, these dialogues champion political liberty, rational debate and rule by law. Articulating the principles behind his lifelong goal of harmonizing Rome’s competing interests in a just and stable ‘concord of the orders’, they propound a comprehensive vision of civil society directed by an elected elite schooled in rhetoric and philosophy, devoted to constitutional government and able to shape public opinion through effective oratory.

The first of these works, *On the Orator*, explores the role of rhetoric and philosophy in public life. Oratory had long been a potent tool in Roman politics, and Cicero aims to reinforce its prestige and legitimize its influence by showing that its success requires wide learning and sound reasoning. Much of the discussion focuses on education, as he weighs the merits of the traditional Roman emphasis on history, poetry and practical experience against the Greek disciplines of formal rhetoric and philosophy. His model orator, who clearly reflects Cicero’s own proficiencies, unites thorough knowledge of history and law with complete command of logical method, philosophical theory and rhetorical techniques in a Romanized version of Plato’s philosopher-rulers. Both expect philosophical education to produce the best statesmen; but whereas Plato’s ideal hinges on mathematical training and transcendental metaphysics, Cicero proposes a thoroughly pragmatic programme of instruction designed to foster eloquence and informed civic debate.

Cicero delineates the institutional framework behind his conception of leadership in *On the Republic*, which was almost entirely lost until most of the first third was recovered in 1820. Challenging the utopian bent of Greek political theory exemplified by Plato’s *Republic*, Cicero argues that the best constitution, far from being unattainable, was largely realized in Rome, where a unique blend of monarchy, aristocracy and democracy formed a ‘mixed constitution’ that provided a system of government ostensibly stable and just. This account, which recasts Rome’s narrow oligarchy as a paradigm of aristocratic paternalism, rests on an incisive and apparently original analysis of political legitimacy. Defining a republic (*res publica*) as ‘a people’s affair’ (*res populi*) and a people as a community ‘united by consensus about right and by mutual interest’, Cicero criticizes all other constitutions for contravening the people’s rights and interests, then argues that no political system is legitimate unless it distributes legal rights equally to all, but electoral, legislative and judicial authority proportionally according to merit and wealth. Other extant sections of the dialogue classify types of constitution in classical Greek fashion and survey the development of Roman institutions; lost or poorly preserved sections summarized Hellenistic debates about the nature and rewards of justice, discussed Roman education and measured past Roman statesman against Cicero’s ideal. Ending the work is the famous ‘dream of Scipio’, which interweaves astronomy and eschatology to sketch a theodicy that rewrites Plato’s myth of Er in the light of Stoic cosmology and exalts public service by reserving the finest posthumous rewards for outstanding statesmen.

On Laws, a sequel probably left incomplete and published only after Cicero’s death, fills in his constitutional model by outlining a comprehensive legal system. Vying with Plato’s *Laws* this time, he continues his argument that Rome already embodied much of the ideal. His treatment of religion and political administration, which is all that survives, is deeply conservative, largely an explanation and defence of existing statutes and institutions by appeal to Greek theory and Roman history, with proposals for change limited to streamlining and archaizing reforms rather than extensive revision or thorough codification. The work was extremely influential, especially on Christian and early modern thought, because it contains the fullest surviving ancient account of natural law (see Natural law). Drawing heavily on Stoic ideas, Cicero argues that the natural world exhibits a divinely ordained and rationally intelligible order that can be codified in legislation and provides the ultimate tribunal for all positive law.

Civil war interrupted Cicero’s writing and he never returned to constitutional or legal theory. But his very last book rounds out his political thinking by examining the role of personal morality in public life. In the guise of an extended epistle to his son, *On Duties* maps out a code of conduct for the Roman nobility that emphasizes justice, benefaction and public service. The focus throughout is on men of high station and the problems of integrating personal ambitions and social obligations. Borrowing heavily from the Stoic Panaetius (§2), Cicero argues that virtuous conduct is always expedient as well as morally required, and that apparent conflicts between morality and

personal advantage are illusory because virtuous action is always the best option.

3 Scepticism and natural theology

Cicero embraced the sceptical stance of the New Academy in his youth when he studied under Philo of Larissa. Modern scholars debate whether he shifted soon afterward to positions he learned from Antiochus, or remained an Academic sceptic throughout life. But a likely explanation for this debate is the moderate tenor of Cicero's scepticism, which eschews dogmatic certainty but accepts 'convincing' (*probabile*) arguments. Inclined by profession to adversarial argument, Cicero employed the Academic strategy of arguing on both sides of questions in his earlier as well as his later dialogues. But his aim was never suspension of judgment, as in the early New Academy under Arcesilaus (§2). Rather, adopting a pragmatic fallibilism that derives from Carneades (§4) but probably owes most to Philo, he considered the careful weighing of opposing arguments the most reliable route to truth. On this basis, he endorsed an eclectic synthesis of ideas derived mainly from Antiochus and Stoics but also from Aristotle and Plato (whom he styles the prince of philosophers and quotes often in original translations); and while reserving judgment on many theoretical issues, he held firm views about many practical matters of politics and morality.

Cicero discusses his sceptical stance most fully in *Academics*, which inaugurates his second series of dialogues by recounting a pivotal debate within the later New Academy about the nature and possibility of knowledge. Only parts of the work survive. But one fully preserved book (entitled *Lucullus*) summarizes Antiochus' heavily Stoicizing brand of empiricism, then rehearses a battery of sceptical objections drawn mainly from Carneades and Philo. Debate centres on Antiochus' defence of the Stoic 'criterion of truth' (see Stoicism §§12-13), a class of allegedly self-certifying perceptions that would be the source and foundation of any knowledge. Cicero himself delivers the sceptical rebuttal, arguing forcefully that knowledge requires certainty, but that certainty is neither attainable nor necessary for the rational conduct of life. Both sides are powerfully argued, and in line with Philo's fallibilism, readers are obliged to assess which seems more 'convincing'. Though frequently elliptical, the discussion maintains a level of argument rarely matched in Latin before Augustine.

Cicero continued to use this Academic method of presenting opposing arguments in most of his subsequent dialogues. *On the Nature of the Gods* presents two pairs of speeches expounding, then criticizing, Epicurean and Stoic theology. The central issue is not whether gods exist, but rather their role in nature and human affairs. Epicureanism envisages immortals residing far beyond this world and oblivious to human affairs; Stoicism maintains that the world itself is rational and divine, operating in accord with providence to the benefit of humanity; and the Academic critiques, without denying the existence of gods, argue that both schools rely on highly dubious assumptions and wholly fail to prove their cases. The debate covers questions of cosmology at length, including both an impassioned defence and sustained criticism of Stoic arguments from design; and the beliefs and rituals of Greek and Roman polytheism are criticized and reinterpreted throughout. The whole discussion, in its reliance on canons of rational inquiry and analysis, is a model of natural theology. Refusing to rely on revelation or authority, all sides agree that religious issues must be decided by evidence and argument; Stoic appeals to divination and widespread belief in gods, for example, are advanced as inferences to the best explanation. In the end, Cicero endorses the Stoic conception of the world as governed benevolently by divine reason, which he clearly found more compelling both intellectually and morally than either the stark amorality of Epicurean atomism or the official religion of Rome which his public station obliged him to uphold.

Two subsequent works examine related problems of knowledge and causation. *On Divination* presents a richly illustrated defence followed by a scathing critique of various religious claims to foreknowledge. Highlighting epistemological issues, Cicero constructs remarkably balanced cases. The defence, appealing to Stoic arguments that divination is a natural consequence of divine providence and often based on systematic observation, assembles a vast gallery of empirical evidence; his reply, in keeping with the rigorous rationalism of Academic scepticism, challenges the validity of this evidence and argues that divination is inexplicable and inconsistent with the evident regularity of nature. But Cicero, despite ridiculing the defence and pronouncing much of Roman religion sheer superstition, offers no final verdict and endorses traditional rites on grounds of social utility. *On Fate* analyses the closely connected topic of determinism. Cicero defends a theory of free will which he attributes to Carneades, while criticizing the Epicureans for postulating uncaused atomic 'swerves' (see Epicureanism §12), and arguing that the Stoic conception of fate as a universal and eternal causal web precludes voluntary action and moral

responsibility. Detailed analysis of Stoic theories of causation and logical consequence makes this perhaps Cicero’s most exacting work.

4 Humanist ethics

Informing all of Cicero’s work is a profound faith in the natural goodness of humanity and the power of reason to direct and improve human life. The assumptions behind this humanist outlook, which is probably Cicero’s most constructive synthesis of Greek ideas, are systematically examined in *On the Ends of Good and Evil* (usually known as the *De finibus*). Tackling the central question of ancient ethical theory, the dialogue inquires into the ultimate end of human action and how happiness is attained (see Eudaimonia). Paired speeches expound and criticize Epicurean and Stoic accounts of human nature and the status of moral virtue; ending the work and receiving only brief criticism is a neo-Aristotelian account derived from Antiochus. Cicero speaks throughout as an Academic sceptic, arguing that Epicurean hedonism is incoherent and morally subversive, and challenging the Stoic doctrine that moral virtue is the sole good and hence sufficient for happiness. But he commends the moral austerity and theoretical rigour of Stoic ethics, and while he finds the Aristotelian position intuitively attractive and most conducive to public service, he questions whether Antiochus’ view that non-moral interests are also intrinsically good undermines the supremacy of moral virtue.

Setting aside sceptical worries to address practical questions, Cicero explores some applications of his ethical rationalism in two substantial works and a pair of earnest but elegant moralizing essays. *On Duties* employs a Stoic framework to spell out systematic rules of conduct (see §2). *Tusculan Disputations* similarly uses Stoic theory to analyse problems in moral psychology. Adopting a format used by Carneades, Cicero presents five lengthy disquisitions refuting common beliefs about the emotions; but since each speech upholds a Stoic paradox, the result is a sustained defence of Stoic doctrines. Invoking a legion of philosophical and literary authorities, Cicero argues vigorously that philosophy is the medicine of the soul, and that it alone enables us to scorn death, endure pain, overcome grief and other passions, and lead good lives. Much of the argument rests on an acute Stoic analysis of emotions as governed by beliefs. But Cicero’s ideal of rational restraint and self-control as the source of mental tranquillity and happiness distills ideas central to Greek and Roman culture alike. Two shorter dialogues portray eminent Romans from the previous century as sage advisors on more personal topics. *On Old Age* enumerates the lasting rewards of honourable character and education, including a glorious afterlife. *On Friendship* extols a paradigm of aristocratic male companionship based on mutual benefit but also integrity and loyalty. Both works, while distinctly less systematic than Cicero’s other dialogues, exemplify his ability to illuminate vital human concerns with philosophical insight and graceful eloquence.

5 Influence

Cicero was the most influential writer and intellect of his time, and his impact on Western culture has been lasting and profound. His philosophical writings, by forging expressions essential for theoretical discussion, inaugurated over sixteen centuries of philosophy in Latin. They also fuelled the rise of Christianity in the West, as the Latin Fathers mined his dialogues in their campaigns against pagan religion and philosophy (see Patristic philosophy). Augustine, whose life was transformed by the exhortation to philosophy in Cicero’s lost *Hortensius*, drew on his writings extensively, especially in *Against the Academics* and *City of God*. Through these and other writers, most notably Ambrose, Jerome and the pagan Macrobius (whose Neoplatonic commentary on ‘Scipio’s dream’ was widely studied), Cicero’s ideas shaped medieval thought, especially ethics and theories of natural law. His influence reached its zenith in the Renaissance, when Erasmus and other humanists emulated his critical spirit and reaffirmed his secular outlook and ecumenical ideals (see Renaissance philosophy). By making his writings the foundation of a liberal education, they also increased his moral authority; and in the following centuries his ethical and political works (above all *On Duties*, dubbed ‘Tully’s Offices’ in English) fostered the revival of republicanism and the development of liberalism, while his dialogues on religion were inspirational to deism. Voltaire proclaimed him the model of enlightened reason; and Hume was deeply indebted to Cicero, especially in his critique of religious dogmatism and his conception of ‘mitigated’ scepticism. The rise of idealism in the nineteenth century lowered Cicero’s philosophical reputation considerably. But renewed interest in scepticism and virtue ethics, along with improved understanding of Hellenistic philosophy, has in recent decades stimulated intense discussion of his work yet again.

STEPHEN A. WHITE

List of works

Cicero, M.T. (80s BC) *On Invention (De inventione)*, in two books, trans. H. Hubbell, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1949.(Handbook on rhetoric and informal argument; includes Latin text with translation.)

Cicero, M.T. (55 BC) *On the Orator (De oratore)*, in three books, trans. E. Sutton and H. Rackham, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1942.(Dialogue debating the place of rhetoric and philosophy in politics and education.)

Cicero, M.T. (54-51 BC) *On the Republic (De republica)*, in six books, trans. G. Sabine and S. Smith, *On the Commonwealth*, Columbus, OH: Ohio State University Press, 1929.(Dialogue analyzing the structure and legitimacy of the Roman state; less than a third preserved.)

Cicero, M.T. (late 50s BC) *On Laws (De legibus)*, in three books, trans. C. Keyes, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1928.(Dialogue on the Roman legal system; incomplete.)

Cicero, M.T. (46 BC) *Stoic Paradoxes (Paradoxa Stoicorum)*, trans. M.R. Wright, in *On Stoic Good and Evil*, Warminster: Aris & Phillips, 1991.(Short declamations defending six claims of Stoic ethics.)

Cicero, M.T. (late 46 BC) *Hortensius*, ed. A. Grilli, Milan: Istituto Editoriale Cisalpino, 1962.(Lost dialogue proclaiming the value of philosophy; only fragments and reports survive.)

Cicero, M.T. (early 45 BC) *Academics*, trans. H. Rackham, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1933.(Dialogue on the nature and possibility of knowledge. Substantial parts of two versions survive: the second of two books from the first version, entitled *Lucullus* but often called *Prior Academics* or *Academics* II; and the first of four books from a thorough revision, entitled *Varro* but often called *Posterior Academics* or *Academics* I.)

Cicero, M.T. (mid 45 BC) *On the Ends of Good and Evil (De finibus bonorum et malorum)*, in five books, trans. H. Rackham, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 1914; book III trans. M.R. Wright, in *On Stoic Good and Evil*, Warminster: Aris & Phillips, 1991; book V trans. S. White, Oxford: Oxford University Press, forthcoming.(Three dialogues summarizing and criticizing Epicurean, Stoic, and Aristotelian ethical theories.)

Cicero, M.T. (late 45 BC) *Tusculan Disputations (Tusculanae disputationes)*, in five books, trans. J.E. King, Loeb Classical Library, Cambridge, MA: Harvard University Press and London: Heinemann, 2nd edn, 1945; books I, II and V trans. A.E. Douglas, Warminster: Aris & Phillips, 1985 and 1990. (Five disquisitions on topics in moral psychology.)

Cicero, M.T. (late 45 BC) *On the Nature of the Gods (De natura deorum)*, in three books but incomplete, trans. P.G. Walsh, Oxford: Oxford University Press, 1997.(Dialogue summarizing and criticizing Epicurean and Stoic views about divinity.)

Cicero, M.T. (45 or 44 BC) *Timaeus*, ed. R. Giomini, Leipzig: Teubner, 1975.(Latin translation of part of Plato's *Timaeus*: 27d-47b, with gaps.)

Cicero, M.T. (early 44 BC) *Cato the Elder: On Old Age (Cato maior, De senectute)*, trans. F. Copley, Ann Arbor, MI: University of Michigan Press, 1967.(Dialogue on how to live after retiring from public life.)

Cieszkowski, August von (1814-94)

Cieszkowski is perhaps best known for being the first to revise Hegel's philosophy of history into a basis for future social reform. His introduction of the idea of 'praxis' as a synthesis between abstract theory and undirected practice was fundamental in the development of the Young Hegelian school, which formed shortly after Hegel's death and sought the radical transformation of all then-existing political, religious and economic orders.

August was born of a wealthy, aristocratic Polish family. He received an excellent education, particularly in languages. His concern with democratic reform was first shown by his participation in the Polish anti-Russian revolutions of 1830-1. In 1832, he transferred from the Jagiellonian University of Cracow to the University of Berlin. There he joined the circle of Hegel's more liberal interpreters and soon developed an appreciation of the practical possibilities of Hegelian theory.

At the time, most of Hegel's students, inspired by the French Revolution of 1830, were impatient to begin the project which they took to be implied in Hegelian theory: the practical reformation of their age. To this end, both orthodox religion and politics had to be completely revised. Cieszkowski became particularly close to two young professors at the University: Eduard Gans and Carl-Ludwig Michelet. Unlike some of their colleagues, they understood Hegel as supporting liberal doctrines, and they led Cieszkowski towards developing a Hegelian basis for political action. In 1838, Cieszkowski proceeded to revise theoretical Hegelianism in order to reveal its revolutionary content. The result was *Die Prolegomena zur Historiosophie (Prolegomena to the Wisdom of History)*. This work was immediately and enthusiastically approved by the progressive Hegelians, in particular by the extreme 'Young Hegelians' - a group which included such radicals as Moses Hess, Ludwig Feuerbach, Max Stirner, Arnold Ruge, Karl Marx and Bruno Bauer.

Although David F. Strauss' *Das Leben Jesu (Life of Jesus)* (1835-6) is rightly credited with being the first Young Hegelian work, it was nevertheless Cieszkowski's work which set the general pattern for the Young Hegelian school. Prior to it, a major difficulty confronting liberal activists was Hegel's own evident lack of concern with the future course of world history (see Hegel, G.W.F. §8). Hegel's view, expressed throughout his works, held that philosophy played no role in '*teaching* what the world ought to be'. This attitude did not sit well with the Young Hegelians. Cieszkowski proposed a radical restructuring of Hegel's own fourfold division of historical ages (Oriental, Greek, Roman and Christian-Germanic) into a triadic and so more 'dialectical' structure: past, present and future. The past, which linked Adam to Christ, was characterized by a focus on practice; the present, from Christ to Hegel, by a focus on theory. The past, with its direct engagement with the practical and concrete issues of reality, had been followed by an age of equal and opposite focus, one in which theoretical speculation drew mankind away from everyday concerns into an abstract mental realm. The theoretical age, which began with Christ's proclamation of the 'Kingdom of God', asserted the ascendancy of the soul over the body. This age ended in the perfected theory of Hegel. After his final and conclusive theory, the post-Hegelian future would be characterized by a synthesis of past practice and present theory - a new era of 'praxis'. This new division of history obviously justified the study of Hegelian theory by giving theorists a major role in setting a future agenda. Praxis, as expressed in the 'deed' linking the abstract theory of Hegelianism with practical action, would engage future thinkers in an ongoing process of rationalizing the real. In sum, the final result of Hegelian theory was, in a proper dialectical manner, the return of that theory into the practical world from which it had emerged. Cieszkowski's work not only redirected Hegelian interest from religion to politics, but also established a programme for Hegelians. Henceforth, given that Hegelianism was the perfected philosophical theory, there only remained the practical task of conforming the world to it (see Hegelianism §2).

In 1842 Cieszkowski published another philosophical work, *Gott und Palingenesie (God and Regeneration)*, directed against Michelet's reduction of God to an impersonal ideal. For Cieszkowski this implied a failure to grasp the concreteness of the divine personality, and was a step back from the threshold of future praxis into the earlier age of abstract theorizing. However, due to its opaque style and the obscurity of its subject, the work was unsatisfying even to its author.

In the year following the publication of the *Prolegomena*, Cieszkowski visited France, where he become deeply interested in an alternative to German philosophic theory: that is, French economic practice. Moving in the social

circles of such eminent liberal French economists as Auguste Blanqui, Hippolyte de Passy, and P.L.E. Rossi, as well as with such thinkers as Pierre-Joseph Proudhon, Royer-Collard and Louis Blanc, it was not long before Cieszkowski's first economic work appeared: *Du crédit et de la circulation (Concerning Credit and Circulation)* (1838b). It advocated the reform of the monetary system by introducing a new type of interest-bearing note. The work, based upon several years of research into economic issues, proposed to balance both private and public economic interests. In 1844 he wrote a short work proposing a reform of the decadent French Upper House, *De la pairie et de l'aristocratie moderne (On the Peerage and Modern Aristocracy)*. An indirect critique of the French bourgeoisie, it reasserted the need for a strong legislative body representing universal interests, a 'popular patriciate' defending the public order threatened by the anarchic individualism of the Lower House.

After the abortive revolutions of 1848, Cieszkowski became a member of the Prussian Lower House, and supported the cause of Polish nationalism. In 1866 he retired from politics to his estate in Poland, where, until his death, he pursued varied public-interest projects and worked on a lengthy treatise entitled *Ojcze Nasz (Our Father)*. He considered this his major work. But although begun in the 1830s, it remained unfinished at his death in 1894. It is a grand and cloudy romantic vision of a political order inspired by theological principles - principles which Cieszkowski thought were embedded in the Lord's Prayer. The Prayer was the revelation of God's plan, the divine praxis required for the establishment of a new and harmonious social order - an earthly 'Kingdom of God'.

Citizenship

Within political philosophy, citizenship refers not only to a legal status, but also to a normative ideal - the governed should be full and equal participants in the political process. As such, it is a distinctively democratic ideal. People who are governed by monarchs or military dictators are subjects, not citizens. Most philosophers therefore view citizenship theory as an extension of democratic theory. Democratic theory focuses on political institutions and procedures; citizenship theory focuses on the attributes of individual participants.

One important topic in citizenship theory concerns the need for citizens to actively participate in political life. In most countries participation in politics is not obligatory, and people are free to place private commitments ahead of political involvement. Yet if too many citizens are apathetic, democratic institutions will collapse. Another topic concerns the identity of citizens. Citizenship is intended to provide a common status and identity which helps integrate members of society. However, some theorists question whether common citizenship can accommodate the increasing social and cultural pluralism of modern societies.

1 Citizenship and democratic theory

‘Citizenship’ is a term the philosophical meaning of which differs from its everyday usage. In everyday speech, citizenship is often used as a synonym for ‘nationality’, to refer to one’s legal status as a member of a particular country. To be a citizen entails having certain rights and responsibilities, but these vary greatly from country to country. For example, citizens in a liberal democracy have political rights and religious liberties, whereas citizens in a monarchy, military dictatorship or religious theocracy may have neither.

In philosophical contexts, citizenship refers to a substantive normative ideal of membership and participation in a political community. To be a citizen, in this sense, is to be recognized as a full and equal member of society, with the right to participate in the political process. As such, it is a distinctively democratic ideal. People who are governed by monarchs or military dictators are subjects, not citizens.

This link between citizenship and democracy is evident in the history of Western thought. Citizenship was a prominent theme among philosophers of the ancient Greek and Roman republics, but disappeared from feudal thought, only to be revived with the rebirth of republicanism during the Renaissance (see Political philosophy, history of §§2, 4). Indeed, it is sometimes difficult to distinguish citizenship, as a philosophical topic, from democracy. However, theories of democracy primarily focus on institutions and procedures - political parties, elections, legislatures and constitutions - while theories of citizenship focus on the attributes of individual citizens.

Theories of citizenship are important because democratic institutions will collapse if citizens lack certain virtues, such as civic-mindedness and mutual goodwill. Indeed, many democracies suffer from voter apathy, racial and religious intolerance, and significant non-compliance with taxation or environmental policies that rely on voluntary cooperation. The health of a democracy depends not only on the structure of its institutions, but also on the qualities of its citizens: for example, their loyalties and how they view potentially competing forms of national, ethnic or religious identities; their ability to work with others who are different from themselves; their desire to participate in public life; their willingness to exercise self-restraint in their economic demands and in personal choices affecting their health and the environment.

2 The responsibilities of citizenship

In ancient Athens, citizenship was viewed primarily in terms of duties. Citizens were legally obliged to take their turn in public office and sacrificed part of their private life to do so. In the modern world, however, citizenship is viewed more as a matter of rights than duties. Citizens have the right to participate in politics, but also the right to place private commitments ahead of political involvement.

An influential exposition of this conception of ‘citizenship-as-rights’ is T.H. Marshall’s *Citizenship and Social Class* (1950). Marshall divides citizenship rights into three categories: civil rights, which arose in England in the eighteenth century; political rights, which arose in the nineteenth century; and social rights - for example, to education, health care, unemployment insurance and old-age pension - which have become established in the

twentieth century (see Rights §§4-5). For Marshall, the culmination of the citizenship ideal is the social-democratic welfare state. By guaranteeing civil, political and social rights to all, the welfare state ensures that every member of society is able to participate fully in the common life of society (see Social democracy).

This is often called ‘passive’ citizenship, because of its emphasis on passive entitlements and the absence of any civic duties. While it has helped secure a reasonable degree of security, prosperity and freedom for most members of Western societies, most theorists believe that the passive acceptance of rights must be supplemented with the active exercise of responsibilities and virtues. Theorists disagree, however, about which virtues are most important and how best to promote them.

Conservatives emphasize the virtue of self-reliance. Whereas Marshall argued that social rights enable the disadvantaged to participate in the mainstream of society, conservatives argue that the welfare state has promoted passivity and dependence among the poor. To promote active citizenship, we should reduce welfare entitlements and emphasize the responsibility to earn a living, which is the key to self-respect and social acceptance (see Conservatism). Critics respond that cutting welfare benefits further marginalizes the underclass. Also, as feminists note, gender-neutral talk about ‘self-reliance’ is often a code for the view that men should financially support the family while women look after the household and care for the elderly, sick, and young. This reinforces the barriers to women’s full participation in society (see Feminist political philosophy).

Civil society theorists focus on how we learn to be responsible citizens. They argue that it is in the voluntary organizations of civil society - churches, families, unions, ethnic associations, environmental groups, neighbourhood associations, support groups - that we learn civic virtues. Because these groups are voluntary, failure to live up to the responsibilities they entail is met with disapproval rather than legal punishment. Yet because the disapproval comes from family, friends and colleagues, it is often a more powerful incentive to act responsibly than punishment by an impersonal state (see Civil society).

The claim that civil society is the seedbed of civic virtue is debatable. The family teaches civility and self-restraint, but it can also be ‘a school of despotism’ that teaches male dominance over women. Similarly, churches often teach deference to authority and intolerance of other faiths; ethnic groups often teach prejudice against other races, and so on.

Liberal virtue theorists emphasize the importance of citizens’ ability to engage in public discourse. This does not mean simply making one’s views known. It also involves the virtue of ‘public reasonableness’. Citizens must give reasons for their political demands, not just state preferences or make threats. Moreover, these reasons must be ‘public’ reasons, in the sense that they are capable of persuading people of different faiths and nationalities. It is not enough to invoke scripture or tradition; a conscientious effort is required to distinguish those beliefs which are matters of private faith from those which are capable of public defence.

Where do we learn this virtue? Liberal virtue theorists often suggest that schools should teach children to distance themselves from their own cultural traditions when engaging in public discourse and to consider other points of view. However, traditionalists object that this encourages children to question parental or religious authority in private life. Those groups which rely on an uncritical acceptance of tradition and authority are threatened by the open-minded and pluralistic attitudes which liberal education encourages. Hence some religious groups see compulsory liberal education as an act of intolerance towards them, even if it is carried out in the name of teaching the virtue of tolerance (see Toleration).

Civic republicans offer another approach to responsible citizenship. In its most general sense, ‘civic republican’ refers to anyone who believes in the need for active and responsible citizens. But there is a narrower conception of civic republicanism, distinguished by its belief (following Aristotle) in the intrinsic value of political participation. Such participation is, in Adrian Oldfield’s words, ‘the highest form of human living-together that most individuals can aspire to’ (1990: 6). On this view, political life is superior to the merely private pleasures of family, neighbourhood and profession, and so should occupy the centre of people’s lives.

This view conflicts with modern understandings of the good life in the Western world. Most people today find the greatest happiness in their family life, work, religion or leisure, not in politics. Political participation is seen as an occasional, often burdensome, activity necessary to ensure that government respects and supports people’s freedom to pursue their personal projects and attachments. The assumption that politics is primarily a means to

protect and promote private life underlies most modern views of citizenship. This attitude may reflect the impoverishment of public life today, compared to the active citizenship of ancient Greece. Political debate seems less meaningful, and people feel less able to participate effectively. But it also reflects the enrichment of private life, given the increased prominence of romantic love and the nuclear family (with its emphasis on intimacy and privacy); increased prosperity (and so richer forms of leisure and consumption); and modern beliefs in the dignity of labour (which the Greeks despised). The call for active citizenship today must compete with the powerful attractions of private life (see Liberalism §§3-4).

3 Citizenship, identity and difference

Citizenship is not just a status, defined by a set of rights and responsibilities. It is also an identity, an expression of one's membership in a political community. Moreover, it is a shared identity, common to the diverse groups in society. Citizenship therefore serves an integrative function. Extending citizenship rights has helped integrate previously excluded groups, like the working class, into society.

Some groups, however - for example, African-Americans, indigenous peoples, ethnic and religious minorities, gays and lesbians - still feel excluded from the mainstream of society, despite possessing the common rights of citizenship. According to cultural pluralists, citizenship must reflect the distinct sociocultural identity of these groups - their 'difference'. The common rights of citizenship, originally defined by and for white men, cannot accommodate the needs of marginalized groups. These groups can only be fully integrated through what Iris Marion Young calls 'differentiated citizenship' (1989). That is, the members of certain groups should be incorporated into the political community, not only as individuals, but also through the group, and their rights should depend in part on their group membership.

This view challenges traditional conceptions of citizenship, which define citizenship in terms of treating people as individuals with equal rights under the law. This is how democratic citizenship is standardly distinguished from feudal and other pre-modern views that determined people's political status by their religion, ethnicity, class or gender. The idea of differentiated citizenship, therefore, is seen by many as a contradiction in terms. Moreover, if groups are encouraged by the very terms of citizenship to turn inward and focus on their 'difference', how can citizenship provide a source of commonality and solidarity for the various groups in society?

It is important to distinguish here two broad categories of differentiated citizenship. For some groups - such as the poor, women, racial minorities and immigrants - the demand for group rights is usually a demand for greater inclusion and participation in the mainstream society. For example, these groups may feel underrepresented in the political process due to historic barriers, and so seek special group-based representation (see Representation, political §2). Or they may want the school curriculum to recognize their contributions to society's culture and history. Or they may seek exemptions from laws that disadvantage them economically, given their beliefs and practices. These groups share the goal of national integration - that is, that historically disadvantaged groups should become full and equal participants in the mainstream society. They simply claim that recognition and accommodation of their 'difference' is needed to ensure integration.

Other groups demanding differentiated citizenship reject the goal of national integration. They wish to govern themselves, apart from the larger society. This is particularly true of national minorities - that is, distinct historical communities, occupying their own homeland or territory and sharing a distinct language and history. These groups find themselves within the boundaries of a larger political community, but claim the right to govern themselves in certain matters in order to ensure the free development of their culture. What these national minorities want is not primarily better representation in the central government, but rather the transfer of power from the central government to their own communities, often through some system of federalism or local autonomy (see Federalism and confederalism). Rather than seeking greater inclusion into the larger society, they seek greater autonomy from it.

This sort of demand challenges traditional accounts of citizenship identity, which presuppose that people view themselves as members of the same society. If democracy is the rule of the people, demands for self-government raise the question of who 'the people' really are. National minorities claim that they are distinct 'nations' or 'peoples', with inherent rights of self-determination which were not relinquished by their (often involuntary) federation with other nations within a larger country. Self-government rights divide the people into separate

peoples, each with its own rights, territories and powers of self-government; and each, therefore, with its own political community. If citizenship is membership of a political community, then self-government rights give rise to a sort of dual citizenship, and to conflicts about which community - the national group or the state - citizens identify with most deeply. Moreover, if limited autonomy is desirable for a national minority, why not secede completely and have a fully autonomous nation-state?

In effect, countries with national minorities face the problem of conflicting nationalisms (see Nation and nationalism). The state seeks to promote a single national identity through common citizenship; the minority seeks to promote its distinct national identity through differentiated citizenship. Finding a source of social unity in such multination countries is a fundamental question facing theorists of citizenship.

Civil disobedience

According to common definitions, civil disobedience involves a public and nonviolent breach of law that is committed in order to change a law or policy, and in order to better society. More, those classed as civilly disobedient must be willing to accept punishment. Why is the categorization of what counts as civil disobedience of practical importance? The usual assumption is that acts of civil disobedience are easier to justify morally than other illegal acts. Acts of civil disobedience, such as those committed by abolitionists, by followers of Mahatma Gandhi and Martin Luther King, Jr and by opponents of the Vietnam War, have been an important form of social protest.

The decision as to what exactly should count as civil disobedience should be guided both by an ordinary understanding of what the term conveys and by what factors are relevant for moral justification. For justification, nonviolence and publicness matter because they reduce the damage of violating the law. Tactics should be proportionate to the evil against which civil disobedience is aimed; someone who assesses the morality of a particular act of civil disobedience should distinguish an evaluation of tactics from an evaluation of objectives.

1 What constitutes civil disobedience?

People care about definitions of civil disobedience because they believe that acts of civil disobedience are easier to defend than ordinary illegal acts. To understand that assumption, it helps to see how any approach to civil disobedience fits within a larger sense of the moral wrongness of most law breaking. Reasons against violating the law are founded on moral rights or justice (deontological reasons) or on harmful consequences (consequential reasons) (see Deontological ethics; Consequentialism). Many acts that breach standards of criminal and civil law are independently immoral. Thus, murders breach the moral rights of victims and are undesirable measured by consequences. Whether or not people have some general responsibility to obey the law, simply because it is the law, the existence of duties to other members of the community and reasons of consequence support keeping the law on many other occasions. For instance, at least within a fair and reasonably effective legal system, taxpayers should pay their taxes (see Obligation, political).

For acts of civil disobedience to be morally justified, reasons in their favour must outrank or outweigh whatever moral reasons lie behind obeying the law. The significance of an act's constituting civil disobedience is that reasons in favour of obedience are reduced or reasons for disobeying are strengthened, or both. An approach to what counts as civil disobedience should be responsive to widespread understanding of the term's meaning and to factors that matter morally.

Any effort to isolate the phenomenon of civil disobedience must distinguish between what we may call full disobedience of law and violating some 'lower'-level rule whilst hoping or expecting that one will be regarded as justified by some higher *legal* rule. In regimes with written constitutions, for example, someone may claim a constitutional privilege to disobey a statute. Such an action, based on an accepted constitutional right, is not true civil disobedience. However, classification becomes more troublesome when someone breaks a law believing that the law should be declared unconstitutional, but strongly expecting that courts will disagree. This essay disregards this subtlety and concentrates on persons who lack any serious claim that their behaviour is protected by another, higher legal rule.

People usually disobey laws from self-interest or strong emotion, without any belief that they are justified morally. But not infrequently people think they have good moral reason to disobey. They may believe that because the precise terms of a law are not regarded seriously or are widely disobeyed, they have little moral reason to obey. (Many Americans feel this way about speed limits on highways.) Even when they perceive substantial reasons to obey, people may think disobedience is justified because they cannot conscientiously perform the required acts, because they face conflicting moral claims in the circumstances or because they seek to achieve broader social goals. The first sort of reason is exemplified by the refusal on a religious basis to submit to conscription. Those engaging in these conscientious refusals would welcome legal change, but their disobedience has a more personal point. Someone who lies under oath to protect a friend lacks such a conscientious objection, but may believe duties of friendship are stronger than the responsibility to testify truthfully. Other illegal acts have some broader social objective. Acts of civil disobedience have such broader social objectives.

An extremely expansive definition of civil disobedience is any ‘deliberate violation of law for a vital social purpose’ (Zinn 1968: 39). According to this definition, the poisoning of Rasputin, and even the rape of Muslim women in Bosnia - if done to help impose Serbian rule - would qualify as civil disobedience. Such an understanding strays too far from the basic conception that ‘civil’ in ‘civil disobedience’ relates not only to the civil order but also to the kinds of tactics that are used. On this view, ‘civil’ is opposed to ‘violent’, although the line between the two is hardly transparent (see Violence).

At the other end of the spectrum of definitions is John Rawls’ account (see Rawls, J. §4). Rawls states that someone who engages in civil disobedience ‘invokes the commonly shared conception of justice that underlies the political order’, declaring that principles of justice are not being respected and aiming to make the majority reconsider the justice of its actions (1971: 364-5). This approach is part of Rawls’ comprehensive theory of justice for liberal democracies (and does not indicate what counts as civil disobedience for tyrannies). Although not ruling out all other forms of resistance for democracies, Rawls thinks acts of civil disobedience are easier to justify.

Rawls’ account disqualifies many acts commonly regarded as involving civil disobedience. Vegetarians publicize their moral abhorrence of killing animals for food by blocking entrances to stockyards; pacifists trespass peacefully on an army base to object to a popular war. In countries where dominant views are neither vegetarian nor pacifist, such demonstrations do not qualify as civil disobedience for Rawls. Analysis is more complicated if objectors trespass on nuclear power facilities. A demonstrator convinced that shared principles of justice have not been respected will be engaging in civil disobedience, but one who sees the problem as one of government stupidity will be doing something else. Such shades of evaluation probably should not determine whether someone’s participation constitutes civil disobedience.

Rawls’ idea that civil disobedience makes the majority reconsider the justice of its actions oversimplifies the objectives underlying most such activities. Suppose people block construction work where officials have approved destruction of a forest in order that expensive housing may be build. The demonstrators have a triple message: that the government acted unjustly on the facts available; that the government should now change course in light of the demonstrated intensity of opposition; and that inconvenience and embarrassment will attend continuation of the present policy. Demonstrators often seek to manipulate costs and benefits to persuade officials that the present course is too expensive. *Pure* appeals to justice are rare; civil disobedience usually involves calculated elements of pressure. Some of Rawls’ definitional criteria may be better understood as factors relevant to deciding whether acts of civil disobedience are justified. For deciding that acts count as civil disobedience, an account drawn from common definitions is preferable.

2 Justifying civil disobedience

The main argument in favour of engaging in civil disobedience is that an overt violation of law may be effective in a way that neither ordinary speech nor lawful demonstrations can achieve. If one’s objectives are important enough, reasons in favour of obeying the law may be overridden. Acts of civil disobedience do less damage to the values of law observance than do most other violations of law that are intended to achieve similar objectives.

The requirement of nonviolence is directly relevant to the issue of damage. Acts of civil disobedience typically cause inconvenience, to a greater or lesser degree. Some also involve breaches of property rights, such as trespasses. However, they do not threaten the safety of persons, the most important interest that the law protects.

The publicness of civil disobedience is mainly significant because it ensures that violators can be identified and arrested, and can be punished if authorities proceed against them. Voluntary submission to punishment goes some way towards satisfying one’s duty to be fair to others in respect to law. Ordinary violations of law take advantage of those who ‘play by the rules’. But when people act openly in a way that makes punishment simple, they implicitly declare that they seek no personal advantage from their action and are willing to pay the appropriate penalty. They also openly commit their fate to legal processes. Even if submission to punishment does not *fully* satisfy a duty of fairness in respect to law, it reduces greatly the degree of unfairness (see Crime and punishment §1). The consequences of illegal action are also different when violators act openly and submit to punishment. The frustration, resentment and insecurity people feel when their interests are jeopardized are reduced if they realize that those who threaten them are willing to pay an even more costly price. By acting openly, the violators demonstrate the depth of their convictions, showing that they take their claims very seriously. They also signify

their respect for their fellow citizens and for the law, especially if they not only submit to punishment willingly but also acknowledge its appropriateness. Openness also reduces the destructive potentiality of illegal actions as examples to others with various social grievances.

Since the main significance of publicness or openness is in its connection to identification and punishment, openness should be understood in a way that corresponds with this significance. Suppose war protesters surreptitiously enter a government office at night, pour blood on some military files and openly declare the following morning exactly what they have done and why. This behaviour may count as ‘open’ for the purpose of classification as civil disobedience, even though the violation itself was covert. Some open actions do not involve the element of submission to punishment. If police who know they are easily identifiable block traffic but are counting on their bargaining power as indispensable peace keepers to ensure that no punishment is imposed, their unwillingness to submit to the law is little affected by the openness of their actions. For this reason, their behaviour probably should not count as civil disobedience.

What constitutes the conditions for civil disobedience to be morally justified? Perhaps the most common suggestion is that lawful means of protest have been pursued unsuccessfully. This condition makes obvious sense. If a law or policy may be altered by legal means, resort to more drastic illegal means is not yet appropriate. Thus, speeches, letters to politicians and lawful demonstrations should precede unlawful demonstrations. The principle is sound, although people often disagree over when lawful means have proved unsuccessful. The principle does not apply in its usual form in emergency situations, say when the government undertakes an unexpected invasion of another country, and, perhaps, it does not apply when the unproductiveness of legal means of protest is patently clear in advance.

Former US Supreme Court Justice Abe Fortas once suggested that disobedience is never justified unless the law being violated is the target of the protest (Fortas 1968). Although disobedience is usually easier to justify when a close connection exists between the injustice people protest against and the law they disobey, no absolute principle of the kind Fortas proposed is defensible. Among other objections, the principle might leave some laws and policies - for example, a highly unjust definition of treason or an egregious use of military force abroad - entirely immune from law-violating protest; and it would also preclude such protests for the government’s failure to enact laws to prevent injustice.

Rawls has proposed that ordinarily, justified civil disobedience will be limited ‘to instances of substantial and clear injustice, and preferably to those which obstruct the path of removing other injustices’ (1971: 372). The clearer an injustice, the stronger the justification for illegal protest. But what of parents blocking a street in order to get a traffic light installed? Contained instances of civil disobedience may be warranted to combat less than grave injustices, so long as the tactics used are not disproportionate to the evil that they protest against. Rawls’ insistence that protesters appeal to a shared sense of justice might be taken as a condition for justified civil disobedience in a liberal democracy (even if it is rejected as a criterion of what constitutes civil disobedience). When protesters do appeal to a shared sense of justice, they importantly indicate their fidelity to the existing political system. But one should not rule out the possibility that civil disobedience may sometimes be justified to shift the moral sense of the community, as in the examples of protests by vegetarians and pacifists, or to respond to stupidity and ineptitude, which parents may see as the dominant obstacle to having the traffic light installed.

Those considering whether civil disobedience is justified will need to consider the likely effects of their actions in accomplishing their objectives. They must also ask whether their actions will have a serious negative effect on political stability or will lead to reprisals against persons whose interests they represent but who do not endorse the tactics they employ.

No easy formula presents itself for determining whether any particular exercise of civil disobedience is justified. Moreover, since civil disobedience typically accompanies highly controversial social issues, even clarity of evaluation is difficult. Suppose ‘pro-life’ demonstrators illegally block access to an abortion facility, believing that actions of this kind can help alert people to the horrors of abortion, save unborn children and increase the likelihood that the law will become more restrictive. Is this civil disobedience justified? A person might think it is not: (1) because all opposition to women’s choice is not justified; or (2) because the protesters’ actions will disserve their own objectives; or (3) because civil disobedience is not warranted, even if one assumes the pro-life view is sound and the protest will have the hoped-for effect. Only the third view directly confronts the

demonstrators' judgment about the appropriateness of civil disobedience as a tactic. Too often, ostensible objections to tactics end up being reducible to disagreement with objectives. Careful, dispassionate analysis is required to focus upon genuine differences of views about the technique of civil disobedience itself.

Civil society

In modern social and political philosophy civil society *has come to refer to a sphere of human activity and a set of institutions outside state or government. It embraces families, churches, voluntary associations and social movements. The contrast between civil society and state was first drawn by eighteenth-century liberals for the purpose of attacking absolutism. Originally the term civil society (in Aristotelian Greek,* politike koinonia*) referred to a political community of equal citizens who participate in ruling and being ruled*

In the twentieth century the separation of philosophy from social sciences, and the greatly expanded role of the state in economic and social life, have seemed to deprive the concept of both its intellectual home and its critical force. Yet, approaching the end of the century, the discourse of civil society is now enormously influential. What explains the concept's revival? Does it have any application in societies that are not constitutional democracies? From a normative point of view, what distinguishes civil society from both the state and the formal economy?

1 Conceptual history

The concept of *civil society* was introduced into modern European political philosophy through Latin translations of the Aristotelian Greek term, *politike koinonia*. In Aristotle's work, *politike koinonia* was defined as an ethical-political community of free and equal citizens who participate in ruling and being ruled under a legally defined system of public procedures and shared values. The term has since come to refer to very different organizations of the sphere regulated by public law - city republics, estate polities, dualistic structures of prince and country, the society of orders within the absolutist state (Riedel 1975). However, the Aristotelian identification of the political and the civil was maintained until the eighteenth century.

The early liberal polemical juxtaposition of society and state, originating in pre-revolutionary intellectual discourses critical of absolutism, decisively affected the meaning of civil society. Ever since, civil society has referred to a sphere of activity and set of institutions outside the state or government, representing an order of legitimacy that properly constructed political organizations ought to serve. The normative ideal of free and equal citizens comprising the body politic (civil society) was retained, but the body politic itself became differentiated in various ways from the state.

Nineteenth-century liberalism in all its versions maintained the society/state dualism. Yet the category of civil society developed primarily at the conservative, revolutionary and republican margins of liberal thought. Although he insisted upon the ethical dignity of the modern state, Hegel (§8) nevertheless conceived civil society as a complex framework of economic activities, legal institutions, intermediary associations and publics upon which modern political culture and identity were to rest (Hegel 1821). Drawing on Hegel's concept of the 'system of needs', Marx (§4) identified the civil with the bourgeois, and reconceptualized civil society from two points of view: as class society and as economic society. Marx also worked with a differentiated model of state and civil society but, unlike Hegel, he sought a revolutionary reunification of the civil and the political (Marx 1843). Finally, Tocqueville worked with a three-part model that differentiated, albeit unsystematically, between a civil society of economic and cultural associations and publics, a political society of local, provincial and national assemblies, and the administrative apparatus of the state (Tocqueville 1835-40).

The professionalization of philosophy and the emergence of differentiated social sciences in the twentieth century seemed to leave the concept of civil society without an intellectual home. Nevertheless it continued to play a role outside, and even within, the disciplines. In Marxian social philosophy, Gramsci (§3) and his followers made the concept of civil society central to their strategy of maintaining a Hegelianized Western Marxism distinct from Soviet Marxism (see Marxism, Western §2). Albeit without using the term, the Durkheimian-Parsonian tradition in sociology continued to develop the idea of intermediary associations and a community of free and equal citizens in order to promote normative integration and combat the atomizing tendencies of the modern state and the capitalist economy. In political theory, the idea of pluralistic limits on the centralizing impulse of the modern state continued to play a role, from Gierke to the British philosophical and the US empirical pluralists. Yet, with the emergence of the structuralist school in Marxism, and the decline of functionalism in sociology and of pluralism in political science, these efforts to translate the originally philosophical concept of civil society into the language of social science and theory apparently came to an end.

2 Revival of the discourse of civil society

Nevertheless, the concept of civil society began to reappear about fifteen years ago in the milieu of neo-Marxist critics of socialist authoritarianism. The pioneering theorists of this revival were Kolakowski, Mlynar, Vajda and Michnik in the East, Habermas, Lefort, Touraine and Bobbio in the West, Weffort, Cardoso and O'Donnell in the South. All knew the works of Hegel, the young Marx or Gramsci and thus had access to the concept of civil society and the idea of a state/society dichotomy. At an earlier stage, neo-Marxists had sought to deepen Marxian social philosophy by drawing upon non-Marxist theorists such as Weber, Simmel, Croce and Freud. They used concepts like alienation, fetishism, hegemony, reification and rationalization to explain and target the endurance of capitalism in the West, as well as new forms of domination and injustice in the East. The recent revival of the concept of civil society seemed to be an analogous move, since its presence in the young Marx justified a critical appropriation of the ideas of another series of non-Marxist thinkers, from Tocqueville to Carl Schmitt and Hannah Arendt (§1).This time, however, instead of invoking Marx to criticize orthodox Marxism, the theorists of civil society located the conceptual origins of communist totalitarianism in the young Marx's demand that the differentiation of state and civil society be overcome (see Totalitarianism). With this self-critique, neo-Marxists became 'post-Marxist'.

The historical success of the revival of the concept of civil society was due to its anticipation of and convergence with a new radical reformist strategy for the transformation of dictatorships, first in the East and subsequently in Latin America. The underlying project of 'societal self-organization' was geared towards rebuilding solidarities outside the authoritarian state. It appealed to a civil public sphere independent of all official, state or party-controlled communication. As a result, there is now vastly expanded discussion, not only in the East (most recently in China) and in the Middle East, but also in many Western countries with established civil societies, where the focus is on the strategic and normative possibilities of further democratizing existing democracies. Yet here too, the discussion has involved an analysis of the specific types of civic solidarities and civil institutions that secure social integration, provide public spaces for participation and reinforce the vibrant civic cultures which, in Robert Putnam's words, 'make democracy work' (1993).

Success in political discourse has led to revival in political science, and to a lesser extent in philosophy and sociology. It has also led to a more explicit critique of the concept.

3 Critiques and responses

On the methodological and analytical levels the concept of civil society is plagued by ambiguities. Even once it is differentiated from political and economic society, it remains unclear what civil society actually comprises. If it entails civil publics, voluntary associations and families, stabilized by basic rights (to association, assembly, expression, press, privacy), we come up against the heterogeneity of these institutions. There are publics in the differentiated domains of society - in science, art, law, religion - admission to which cannot be open to all. Voluntary associations vary in size, purpose, and political function. These in turn differ from social movements, which are also extremely diverse in form and orientation. Family types vary greatly. The question inevitably arises: what is the point of referring to this whole complex as civil society?

One could, of course, ask the same question about the institutions comprising the 'economy' or the 'state'. But in those cases the concepts of money and (political) power do seem to indicate the outlines of differentiation. The concept of communicative action coordination reconstructed by Habermas (1981) may solve the problem in principle for civil society. Yet on the institutional level, ambiguities remain. Surely political parliaments and corporate boards do not exclude deliberation any more than civil associations and publics exclude money or power. Do state, economic and civil institutions have organizing principles that differ in kind or only in degree?

One solution is to argue the distinctiveness of civil society from the normative point of view. The actors and institutions of the polity and the economy are directly oriented to the exercise of state power, to issues of collective goal setting, efficient administration and/or profit. They cannot afford to subordinate strategic or instrumental criteria to those patterns of normative integration that generate solidarities or collective identities and build civic culture and which are characteristic of civil society. Moreover, the publics in state and economic institutions are constrained by pressures of decision-making that preclude in principle the ideal of *open-ended* communication and contestation, an ideal that serves as a standard, however counterfactual, for interaction in civil and associational

publics.

However, even on the level of normative political theory the coherence of the concept of civil society remains in question. Indeed, each of the core elements of civil society has been articulated by *competing* and apparently incompatible traditions of political philosophy. Concerned with the danger of state absolutism, the liberal tradition has focused on individual rights (see Liberalism §3). The threat of anomie and social disintegration in modern society motivates the communitarian's stress on social solidarity, social integration and 'intermediary institutions' (see Community and communitarianism). Fearing corruption paternalism and/or political apathy, republican and democratic theorists focus on civic virtue, participation and public space (see Republicanism). The question remains: can the gaps between these distinct positions be papered over by a conception of civil society that tries to bring together the categories of rights, social solidarity, participation and public space?

The concept of civil society cannot serve as the centrepiece of a political philosophy that is construed either as an alternative to, or a synthesis of, these normative perspectives. Nor can it serve to harmonize competing political projects. However, it can help us to articulate the contested terrain that is at stake in the competing political theoretical traditions. From this perspective, the question is not whether the concept of civil society is still relevant to contemporary political theory, but rather, which version of civil society a particular theoretical approach presupposes. Once this is made clear, the concept can be useful to efforts to develop specific interpretations of rights, solidarities, participatory forms and public spaces that make liberal, communitarian, democratic and republican insights at least compatible. Nevertheless, it is bound to remain what Gallie (1955-6) once called an essentially contested concept.

Cixous, Hélène (1937-)

Hélène Cixous, a prolific French author born in Algeria, works between poetry and philosophy. She is part of a larger intellectual community in France that, since the 1960s, has sought a critique of the Western (male) subject, claiming that the 'metaphysical' notion of the subject has for three centuries contributed to the repression of nature, women and other cultures by construing human existence in terms of the separation of mind from body, and more generally of concept from metaphor.

Influenced by Nietzsche and Freud, Cixous privileges the artistic and poetic but all her work has philosophical underpinnings, especially those proposed by Derrida. Like his, her thought champions notions of difference, multiplicity and life over identity, univocity and death. She seeks to displace the unified, narcissistic (male) subject, which in her view is on the side of death. Cixous is also importantly influenced by her critical reception of Hegel and Heidegger.

Though she declares herself primarily a poet and a thinker, Cixous has kept close ties with the academy and has undertaken a variety of political activities. After helping to found, in 1968, the experimental University of Paris VIII at Vincennes - an institution both politically controversial and intellectually scintillating - she established there, in 1974, one of France's few Centres for Women's Studies. Her seminars have attracted students from around the world and have become, not merely intellectual experiences, but spiritual training grounds. Her struggle for a different approach to the other and for giving a voice to others has led her to espouse many political causes. But politics for Cixous are, like philosophy, never separated from poetry: from the invention of new languages without which, in her words, no social change can come about.

The critique of a subject identified as 'male' leads, from Cixous' earliest work on, to broadly psychoanalytical concerns. Her acute perceptions of others' psychic 'vibrations' has made her an excellent reader and critic, as evidenced in the early essays on Freud, Joyce, Kleist, and Poe collected in *Prénoms de personne* (1974). But she has also subjected psychoanalysis to intense, deconstructive scrutiny, in which supposed psychoanalytic 'truths' are rejected in favour of open-ended, personal narratives. Her avant-garde writings of the late 1960s and early 1970s conceived of a subject that is no longer masterful and autonomous but always in dialogue - or transference - with other textual or living subjects or voices. In this conception, the subject constructs itself, or is actively 'born' and 'reborn', at the interstices of various texts and history. The philosophical underpinning for this is a critique of Hegel and his brand of dialectical reasoning, as exemplified in the account of the master-slave relation in the *Phenomenology of Spirit* (see Hegel, G.W.F §5) - a relation which Cixous sees as the basis of much of Western dualistic thinking, including the existential humanism of Sartre and de Beauvoir.

In one of her most widely read books, *La Jeune Née* (*The Newly Born Woman*) (1975) co-authored with Catherine Clément, Cixous began a lengthy detour through the cause of women. In this phase of her work, she 'deconstructively' criticized symbolic practices that organize culture through hierarchically ordered oppositions such as nature/culture, speech/writing and man/woman (see Deconstruction). These oppositions, themselves produced historically, were to be displaced into mere differences. The simultaneous exclusion in metaphysics of the terms 'writing' and 'woman', argued for by Derrida, enabled her to coin the productive but controversial expression, 'feminine writing' (*écriture feminine*). This phrase, read in the derivative sense of a woman writing, was used to raise consciousness. But in a Derridean sense, writing is always related to and occurs within an (unconscious) scene. Thus, Cixous argued that the body is never a brute given but is always already encoded, and disarms accusations of essentialism. '*I*' is more than one, for it is in constant dialogue with others, and any identity is imposed from the outside. Cixous destabilized the fixed sexual identities imposed by a reigning cultural order through her concern with bisexuality.

In Cixous' enterprise of feminine writing, philosophy intersects with anthropology as well as with psychoanalysis. Bataille's reading of Mauss's classic essay, *Essai sur le don (The Gift)* (1925) prompted her to look at cultures that practise modes of exchange different from those of Western retention and accumulation (such as Kwakiutl tribes, known for their ritual of *potlatch*). This led her poetically to invent ways of giving and receiving unconditioned by a restricted (male) economy infused with feelings of guilt and debt. She argued that women, because of their marginal status in society, practise the art of the gift more often than men, who are caught in scenarios of

castration. ‘Feminine writing’ itself therefore exemplified an art of giving at the level of content and form. Her texts, speaking of generosity, exemplify it through an excess of meaning. In this, ‘feminine’ serves to designate, not an enduring attribute, but a transitional step toward other modes of exchanging where it will be replaced with other adjectives.

In the early 1980s, Cixous’ critique of the Hegelian dialectic of recognition and sublation gave way to other approaches. Her reading of the Brazilian novelist, Clarice Lispector, first published in the review *Poétique* in 1979, inaugurated a shift toward Heidegger’s philosophy of language. With it came a change in style. Emphasis on surface gave way to depth; earlier ‘explosions of the subject’ were discarded in favour of a return to ‘man’ (*l’homme*). Heidegger’s notion of poetry, a *technē* that he favours over instrumental technology of repression, was welcomed. In this stage of her work, Cixous combined her devotion to writing more explicitly with philosophy, as a new brand of ‘writing-thinking’ enabled her to work through personal, cultural and historical issues. Her texts of this period are concerned with philosophical questions such as, who leaves and who arrives where? How does one give and receive? How does one have what one has? Her continued dialogue with Derrida also led her to deal with questions similar to his, such as the promise and the secret.

In her recent work, the emphasis on individual pleasure (*jouissance*) fades. Her concern with the cause of women, though not abandoned, opens out to others. This is evident in her writings for the theatre. Her plays on Cambodia (1985) and India (1987), on apartheid and the gulag (*Manne*, 1988) broach issues of history and collective voice in terms of neo-colonialism. All these plays and texts oppose a lofty sphere of combat for truth to a low sphere of political battles and sheer power. In this period Cixous has continued her personal meditations, now focusing on her childhood and her Jewish origins. She is also returning more to the classroom, navigating deftly between national literatures and philosophies, between genres and media.

How such a hybrid writing-thinking fares either as poetry or as philosophy remains to be seen. To date, all of Cixous’ production, whatever its genre, has been critical of metaphysical closure and its repressive conceptual and syntactic structures. Her reading and writing of differences performed through a variety of topics undo totalizing systems based on inclusion, exclusion and negation - or, in psychoanalytic terms, on castration. Yet birth - no longer just anatomical and natural - and *sorties*, ways out, do not simply lead to an outside. They must, for Cixous, be continually re-enacted in an ongoing writing-thinking at the interstices of personal, cultural and social history.

Clandestine literature

Clandestine philosophical (anti-Christian) literature of the seventeenth century circulated in manuscript form until its publication by the philosophes *in the later eighteenth century. Since research began, the list of texts has grown and now includes some 260 titles which cover the classical heritage of the Renaissance, the works of La Peyrère and Cyrano, the influence of Spinoza, the growth of rationalism which accompanied the splintering of Protestant churches and sects, and the development of the deist debate in Britain.*

Clandestine philosophical literature has been considered a serious object of study since 1912 when G. Lanson discovered a number of manuscript copies of 'philosophical' (that is, anti-Christian) texts in French public libraries. The search for such texts was pursued by I.O. Wade (1938), stimulated by N.L. Torrey's work on Voltaire's library in St Petersburg. Wade thus put forward a list of 102 philosophical texts distributed between 1700 and 1750. These results have been extended by recent research, in particular by M. Benítez, and some 260 titles distributed in Europe from the sixteenth to the eighteenth century are now known. New discoveries will certainly be made and new texts revealed, as suggested by the catalogues of private libraries of that period. This literature raises questions for philosophy, intellectual history, apologetics, printing and the book-trade; it constitutes the roots of anti-Christian thought in the eighteenth century, and the texts of the prestigious *philosophes* of the Enlightenment must now be related to this intellectual context.

The development of this field of study has raised new problems. Research now covers the sixteenth, seventeenth and eighteenth centuries, and there is great risk of anachronism in the interpretation of early texts in relation to later events. Nevertheless, currents of thought can be defined which act as signposts from one century to the next: the clandestine philosophers of the eighteenth century regarded themselves as inheritors of a long anti-Christian and anti-ecclesiastical tradition.

In France, this anti-Catholic literature is not to be confused with Protestant, Socinian, Anabaptist or even Jansenist polemics, but the multiplication of sects and churches had an obvious effect on clandestine authors, who represent all possible positions in relation to Catholic orthodoxy (see Socinianism). In this sense, the barrier between orthodoxy and heterodoxy becomes vague and confusing. Recent research on Spinoza and the Dutch 'collegiants' (such as Bredenburg) has illustrated how philosophical rationalism was enriched by religious thought. A symmetrical development of philosophical ideas within Christian apologetics is evidence of prevalent uncertainty towards traditional barriers between deism and Christianity, belief and unbelief. The 'inner light' and the philosophical 'Enlightenment' enriched each other.

Similar relations can be discerned in the distribution of clandestine literature. The archives of the Bastille yield few names of clandestine philosophers, but reveal the full breadth of unorthodoxy and the full weight of the censorship prevalent in the seventeenth century. The successive waves of Huguenots and Jansenists are easy to discern: throughout the classical age book-pedlars and printers of political, religious or obscene pamphlets are imprisoned; the diffusion of philosophical ideas thus follows in the footsteps of other unorthodox currents of thought. Philosophical writings are distributed by specialists in political satire, in Marrano, Protestant and Jansenist propaganda. The history of clandestine ideas in Europe is thus closely linked to the history of the book-trade and censorship.

An important aspect of 'scribal publication' in the seventeenth century has been underlined by H. Love (1993). The manuscripts, of course, preceded the printed work, but they survived beyond the printing of the text (or rather, one version of the text) and continued to be amended and altered by subsequent scribes: in this sense, they are evidence of the evolution of philosophical ideas. Clandestine literature can thus be studied from the point of view of textual genetics: variants are to be interpreted not as mistakes, not as lessons unfaithful to the original, but as indications of a living and changing philosophy.

Clandestine philosophical literature reflects the main currents of intellectual history and reveals their significance for anti-Christian thought. Thus, in 1659 an enormous compendium of classical thought was constituted under the title *Theophrastus redivivus*, presenting the classical heritage in the form of extracts from ancient authors on a variety of crucial themes: the existence of the gods, the nature of the material world, the status of religion, the

existence of the soul, the existence of hell, the consequences of physical death, the precepts of life according to Nature and so on. It is an anthology of free thought concocted from Ancient texts. At the same period, various versions of Cyrano de Bergerac's *L'Autre monde* were distributed, and Isaac La Peyrère composed his vast trilogy which leads us from the 'pre-Adamites' to the conversion of the Jews. A number of manuscripts reflect debates around the 'new philosophy' of Descartes and a dozen texts deal with aspects of Spinoza's philosophy. Clandestine philosophical literature of the end of the seventeenth century thus developed in the intellectual context of the rivalry between the 'systems' of Descartes, Gassendi, Hobbes, Malebranche, Spinoza and Locke - and soon of Leibniz. Machiavelli, Naudé, La Mothe Le Vayer, Hobbes, Vanini were systematically exploited, while Montaigne and Bayle were inexhaustible sources of plagiarism and imitation. The English context of debates around Deism weighed heavily on the evolution of French thought: Toland, Collins, Tindal, Mandeville, Blount, Middleton, Bolingbroke and Woolston were soon to be translated, as also were the Marranos Isaak de Troki and Orobio de Castro (see Deism).

Clandestine philosophical literature can thus be interpreted within the context of the history of philosophical scepticism recently traced by R.H. Popkin and others. Central to this history in the seventeenth century was the rivalry between the Pyrrhonism inherited from Montaigne by La Mothe Le Vayer, Gassendi and Pascal and the rationalism developed by Descartes, Malebranche and Leibniz (see Pyrrhonism; Rationalism). The philosophy of the Enlightenment can thus be shown to derive from a crisis in Christian philosophy of the seventeenth century.

Clarembald of Arras (1110/20-*c*.1187)

A teacher of philosophy at Laon and commentator on Boethius, Clarembald was a product of the School of Chartres. His principal philosophical work, the Tractatulus (Short Treatise on Genesis), is an attempt to link Platonic theories of creation with the account given in Scripture, and includes a discussion of the nature of form and matter.

Clarembald most likely was born between 1110 and 1120. He studied at Paris under Thierry of Chartres and Hugh of St Victor in the late 1130s, and directed the schools of Laon for a short while around 1160. Most of his life, however, was an active one: he was provost and archdeacon of the diocese of Arras, and was chaplain in Laon during the last years of his life.

Clarembald's principal philosophic work links him to the school of Chartres. He wrote an introductory letter to Thierry of Chartres' *De sex dierum operibus (On the Works of the Six Days of Creation)* and a *Tractatulus (Short Treatise on Genesis)*. In the introductory letter, Clarembald claims credit only for the special effort he has made in his *Tractatulus* 'to reconcile many views of the philosophers with the Christian truth so that the word of Scripture might receive strength and protection even from its adversaries.'

The *Tractatulus* thus attempts to reconcile the portion of Plato's *Timaeus* that was translated and commented on by Calcidius with the message of Genesis as interpreted by Ambrose, Augustine, Isidore of Seville and Bede. The scriptural account, according to Clarembald, does not conflict with philosophical explanations of order in the world. The opening words of Genesis, 'In the beginning God created heaven and earth', bring out the deeper meaning of philosophical arguments. They provide an introduction, even for pagans and non-believers, to a knowledge of the Creator. The world (heaven and earth) is made up of contrary elements: hot ones and cold ones, moist ones and dry ones. It is either nature, chance or a maker that has joined together these opposed elements. Nature cannot produce such an order, since it unites only things that are alike; neither can chance produce such a universe, since chance presupposes already existing causes that come together to produce an unexpected happening. These causes thus would be prior to chance, the agent that allegedly joins them together. The only cause capable of uniting these contrary elements into an ordered whole is their maker, the Creator who brought these elements into existence.

The Genesis account adds that 'the earth was void and empty'. Augustine (§8) speaks of the primordial matter as 'formlessness', or the capacity to receive a form. Plato (§16) describes the same formless matter as that which exists between nothingness and substance. His pupil Aristotle (§12) at times calls this *aptitudo* (ability), and at times *carentia* (lack of form). We grasp it, according to Clarembald, by removing forms. When we remove from a formed object its forms, then nothing remains but the potential to receive these forms. If we take away the form of a brass statue, for example, then only the brass is left; if we strip the brass of its properties, then only the element of earth remains. If we remove the characteristics of earth (dryness and frigidity), then that which remains is not nothing, but formless matter. Such formless primordial matter is called by the philosophers *possibilitas* (potency), since it is capable of receiving all forms. When it receives such forms, then it becomes *possibilitas definita* (specified possibility) (see Matter).

Formless matter does not receive its forms from itself, but from what the philosophers call *necessitas absoluta* (absolute necessity). 'Absolute necessity', according to Clarembald, is what Boethius calls 'Divine Providence', what Augustine names 'Word' or 'Divine Wisdom' and what Pythagoras describes as 'One'. 'Divine Wisdom' implants *rationes seminales* (seminal reasons) in the formless matter and it is by means of them that things reproduce other things of the same kind. These seminal reasons, or what the philosophers call *similitudines nascendi* (reproductive likenesses), account for the normal course of nature (see Augustine).

Clarembald's earlier commentaries on Boethius' *De trinitate (On the Trinity)* and *De hebdomadibus (On the Groups of Seven)* already make many of the philosophic points he develops in the *Tractatulus*, but they also reveal his view of the nature of a properly conceived and formulated *quaestio* (question) (Commentary on *De trinitate* Prol. 5-14), his theory of the categories (Commentary on *De trinitate* 4, 1-46), the distinction between dialectical, demonstrative and sophistical syllogisms (Commentary on *De hebdomadibus* i, 1-2), and his interpretation of

Boethius' different levels of abstraction (Commentary on *De trinitate* 2, 17-9). Although strongly influenced by Thierry of Chartres and Hugh of St Victor, Clarembald was on theological issues also a strong critic of Peter Abelard and a more cautious opponent of Gilbert of Poitiers.

Clarke, Samuel (1675-1729)

Regarded in his lifetime along with Locke as the leading English philosopher, Clarke was best known in his role as an advocate of a thoroughgoing natural theology and as a defender of Newtonianism, most notably in his famous correspondence with Leibniz. His natural theology was set out in his Boyle lectures of 1704 and 1705, but it left little room for revelation, and endeared him to neither side in the quarrel between deists and orthodox Anglicans. A staunch proponent of Newtonian natural philosophy, he defended it against criticisms of its notions of gravity and absolute space.

1 Natural theology

Samuel Clarke was born at Norwich, England, and studied at Gonville and Caius College, Cambridge, where he remained until 1700. He was a fine classicist and while still a student he published a Latin translation of the standard Cartesian natural philosophy textbook of the time, Rohault's *Traité de Physique*, which replaced the inferior translation of Théophile Bonnet (see Rohault, J.). In 1697 he was converted to the cause of Arianism, and from this time until his death in 1729 - after many years as rector of St James's, Westminster and chaplain to Queen Anne - he devoted his main energies to the development of a natural theology.

Among the key theological issues within the Anglican Church at this time were an internal dispute between defenders of the Athanasian Creed (which established the notion of the Trinity) and Arians, and an external dispute between Anglicans and deists. Arianism or unitarianism had significant support within rationalist theology in England in the late seventeenth and early eighteenth centuries. Deism - the notion that there is a natural religion with precedence over any revealed religion - had become a significant force with the posthumous publication of the works of Charles Blount (1654-93) in 1695, and reached its apogee in the 1730s. English deists, unlike French Enlightenment writers, generally considered themselves Christians, with the result that the distance between deists and writers like Clarke, who defended natural theology at the expense of revelation, was sometimes very small.

Clarke's aim was to reconstruct religion and ethics on the basis of natural philosophy and natural theology. His proof of the existence of God is a version of the cosmological argument. Its core is that if something exists now, something always must have existed because things cannot come into existence from nothing; but what it is that always has existed must be 'self-existent', that is, it must depend on nothing else for its existence; and what is self-existent is necessarily existent. All these steps are questionable but, even if supposed valid, the argument establishes a very abstract God rather than a personal God who is moral, just and truthful. Consequently Clarke needed to bridge the gap between this God and the God of Christianity (even in its unitarian version).

His account of God harbours a deep and familiar problem. On the one hand, God is completely free, and orders the world in a way that is constrained by nothing, for nothing could constrain such a perfect being. On the other hand, goodness and truth are not arbitrary, and in particular God's action must reflect natural standards of truth and goodness rather than instantiate such standards arbitrarily. Clarke attempts to reconcile these principles by means of a doctrine of the 'fitness of things', whereby nature has a moral aspect which mirrors its physical aspect, moral and physical aspects both being knowable by reason. The idea is that any rational being will guide its conduct in terms of these moral principles. Since God is completely rational, he follows them of necessity, but we are also influenced by passions which act against reason and cause us to behave immorally on occasion, and it is from this that the need for established religions arises.

2 Doctrine of the soul

The Boyle Lectures were set up - on a bequest of £50 per annum from Boyle - to counter deism, Hobbesianism, atheism and other unorthodox views, and in his Boyle Lectures for 1705 Clarke attacked what he perceived to be the reductionism of Hobbesian and Spinozistic accounts of mind (see Deism §2; Hobbes, T. §3; Spinoza, B. de §§5-6). The problem had come to the fore because of Locke's passing statement that it is not inconceivable that God could 'superadd to matter the faculty of thinking' (see Locke, J. §5). Like other critics of Locke, Clarke believed that this was tantamount to materialism. His response was to deny that perception and intelligence can derive from matter - either reductively or in virtue of a combination of matter and motion - on the grounds that only what possesses a perfection can cause or communicate it: something that lacks the perfection of thought

cannot produce this perfection in something else.

Two critics took Clarke to task - Henry Dodwell and Anthony Collins. Collins, in particular, accuses Clarke of failing to distinguish between the powers of the parts of matter and the powers of organized combinations of parts: the latter powers are different from the former and serve to explain thought and action. Clarke denies that there can be powers in the whole that are not powers of the parts, distinguishing various kinds of genuine from non-genuine properties of things: colours, for example, seem to be properties of the whole but not the part, yet they are in fact not genuine properties of the object at all. Collins accuses Clarke of asserting that the whole cannot have powers lacking in its parts, whereas he should be demonstrating it. The question is not simply one of onus of proof, however, for Clarke himself subsequently admits that something can have qualities or powers, such as roundness, which are not present in its parts. But consciousness, he maintains, is not like this: it is a power which must inhere in the parts if it is to be present at all (see Collins, A. §§3-4).

The dispute is inconclusive, but it hard to avoid the conclusion that Clarke set off on the wrong foot in denying that whole and parts can have different properties, and the claim that consciousness must be in all of the parts is not supported by any compelling argument.

3 Defence of Newton

Clarke is often praised for the way in which his notes to his translation of Rohault undermine Rohault's Cartesianism in favour of a Newtonian account. But in fact the notes to the first edition are very uncritical, accepting the vortex theory and making no mention of gravitation. It was only in later editions that the notes took on a Newtonian edge, and by that time Newton's *Principia* had a wide circulation. Clarke was, however, an able defender of Newtonianism in the 1700s, being the first to distinguish clearly between momentum and kinetic energy, and he was chosen to respond to Leibniz's accusation that the ideas of Newton and Locke were responsible for the decline of religion in England (see Leibniz, G.W. §11).

Some of the questions at issue between Clarke and Leibniz are on points of interpretation, as in Leibniz's rejection of Newton's claim that space is simply God's *sensorium*. Leibniz points out that if God needed an organ to perceive things, those things could not depend on him, and Clarke replies by construing Newton's doctrine as meaning that God is omnipresent and so, far from requiring sense organs, has unmediated perceptual grasp. Other disputes involve substantive questions in natural philosophy, and the fundamentals of Leibniz's philosophy - notably his principles of sufficient reason and the identity of indiscernibles - are called into question. Many of the issues in the dispute are essentially continuations of the clash between Cartesian and Newtonian natural philosophy. Descartes had provided a model in which planets were carried around a centrally rotating sun by the swirling motion of the ether around this sun, an account which dispensed with any need for action at a distance. This is essentially the account that Leibniz defends, and Clarke defends both the existence of a void (which undermines the idea of a swirling ether) and action at a distance, which he points out has been shown to exist, even if its causes have not been discovered.

Other questions in dispute raise new problems, and a key issue is the nature of space and time. Leibniz considered these to be relations, and hence to be relative, whereas Clarke considered them to be real and absolute. Newton had considered that, although we cannot tell of any inertial state whether it is a state of rest or a state of uniform rectilinear motion, there is a way in which we can detect the existence of absolute space, and he believed that the concave deformation of the surface of water in a rotating bucket can only be explained by a rotation relative to absolute space (see Newton, I. §3). Leibniz did not accept that the idea of absolute space made sense, for in such a space no part is different from any other, and there would be no reason for God to create things in one place rather than another. Clarke's response is effectively that God does not need sufficient reason: God creates through an act of will. Moreover, points in space are not merely relational: they have real properties that distinguish them from one another, as the bucket experiment indicates. Clarke is in a strong position here, and the challenge to Leibniz is to indicate how differences in inert forces can be explained except by reference to space and time.

Clauberg, Johannes (1622-65)

Johannes Clauberg was a member of the Cartesian school in the years immediately following Descartes' death, and is extremely important as an early expositor of Descartes and a spirited defender of the Cartesian philosophy. His writings include a number of direct commentaries on Descartes' published works, as well as extensions and elaborations of the master's views.

Clauberg was born to Protestant parents in Solingen, Westphalia. He studied at Bremen, then at Groningen, where the Cartesian Tobias Andraea and the anti-Cartesian Martinus Schoock both taught. In 1646 he visited France and England, and in the late 1640s he studied at the University of Leiden, where he attended the lectures of the Cartesian Johannes de Raey. Clauberg's *Elementa philosophiae sive ontosophia*, published in 1647 although probably written in 1645, was a defence of Aristotelian metaphysics against Ramist attacks, and contains nothing recognizably Cartesian (see Ramus, P.). While it is not impossible that he met Descartes himself, he was probably converted to Cartesianism by either Andraea or de Raey before April 1648, when he transcribed the notes of a conversation between Descartes and the young theologian Frans Burman. In 1649, at the request of Count Louis Henry of Nassau, he was appointed professor of philosophy and theology at the University of Herborn in Germany, where he taught Cartesianism for two years in the face of considerable opposition. The count tried to stabilize Clauberg's position by writing to some Dutch universities for their opinions on the new Cartesian philosophy, and while there were some positive responses, they were too few and too late to make a difference. In 1651, along with the Cartesian Christopher Wittich who was his school friend from Groningen days, Clauberg left Herborn for the University of Duisburg, where he taught until his death.

Clauberg's *Logica vetus et nova* (1654) was an attempt to combine the principles of traditional logic with those of a 'Cartesian' logic, something not unlike what Arnauld was to do in the Port-Royal logic a few years later, despite the fact that Descartes himself rejected the enterprise of formal logic (see Arnauld, A. §2; Port-Royal). His *Metaphysica de ente* (1664), sometimes mistaken for a second edition of his earlier *Elementa philosophiae sive ontosophia*, was in reality a completely separate work, presenting a metaphysics in scholastic style but with Cartesian content. Its subject matter was the science of being as such. Clauberg treated the notions of being, essence, existence, the One, the True, the Good and so on - all found in traditional Aristotelian treatises on metaphysics. However, Clauberg's metaphysics was grounded in the Cartesian distinction between mind and body, which he takes to replace the ten Aristotelian categories as the highest division of things into classes. Again, this is somewhat paradoxical, since Descartes himself seemed to reject the idea of a metaphysics in the sense of a science of being as such. His logic and metaphysics in particular earned Clauberg the reputation of the learned Cartesian, and his presentation of Cartesian ideas in scholastic form, complete with scholarly references, probably eased the way for Descartes' philosophy in the German universities.

Of particular philosophical interest is his *Physica* (1664), a collection of treatises including one on living things and another on the union between mind and body. Like other Cartesians writing in this decade, including the French circle of Cartesians (Cordemoy, La Forge, Clerselier and so on), with whom he was probably in contact, Clauberg put forward a kind of occasionalism (see Occasionalism). First, matter as such is inert, and God is the only genuine efficient cause of motion in the physical world; like Descartes, Clauberg held that the soul or mind, a substance whose essence is thought, is really distinct from body, a substance whose essence is extension. But unlike Descartes, he held that the two are not genuine ('physical') causes of changes in one another, and that mind and body are united simply by virtue of the quasi-causal relations between them. The mind is what he called a 'moral cause' of changes in the body; mind does not create new motion, but only changes the direction of the motion already there, otherwise the Cartesian law of the conservation of quantity of motion would be violated. Conversely, body, being less noble than mind, is only the 'procatarctic cause' of ideas in the mind, giving mind the 'occasion to have these or those ideas, which it always has the power to have within it'.

Cleanthes (331-232 BC)

The Greek philosopher Cleanthes of Assos played a leading role in the formation of Stoicism. He was at once the most physicalist and the most religious of the Stoics. Pupil, and eventual successor (in 262), of the school's founder Zeno, he wrote numerous philosophical works, including some poetry. In particular, he developed the notion of fire as the world's governing principle.

Born at Assos in Asia Minor (modern Turkey), Cleanthes is said to have had his first career as a boxer. Moving to Athens, he joined the newly emerging Stoic school, led by Zeno of Citium. Poverty forced him to work at night, drawing water, and to attend Zeno's classes during the day. He became Zeno's closest ally in the school, and in 262 BC succeeded him as its head. He died at a very advanced age, to be succeeded by Chrysippus.

Cleanthes was a prolific writer: we know the titles of some 57 works. Either in addition to these works, or more probably within them, he composed passages of philosophical poetry, of which his short but very powerful *Hymn to Zeus* survives intact. His philosophical outlook was distinctive in three strikingly different ways. (1) He was the most physicalist of the Stoics, with a special interest in the role of fire. (2) He was perhaps the main logician in the school's first generation, and was probably responsible for developing the key notion of the incorporeal *lekton* (see Stoicism §8). (3) He was the most deeply religious of Stoic thinkers.

Cleanthes, even more than other Stoics, revered Heraclitus as an authority on cosmological matters. From Heraclitus he acquired and developed the doctrine of the primacy of fire, which he viewed as the vehicle of divine 'reason' (*logos*), varying according to its degree of 'tension'. Not only does the world begin and end in fire, as nearly all Stoics agreed (see Stoicism §5), but fire - which includes warmth - is the main creative force throughout nature. Here he was not in actual disagreement with other Stoics, but he was the school's leading fire theorist, while after him the emphasis shifted from fire to *pneuma*, which includes air as well as fire (see Stoicism §3).

Zeno had identified the virtues as various kinds or aspects of wisdom - using a description which left the nature of their unity (see Stoicism §16) unclear. Cleanthes interpreted this as referring to a suitably tensioned 'stroke of fire' in the soul, constituting a kind of mental strength which, in different circumstances, comes to be called 'justice', 'courage' and so on. While not incompatible with the usual Stoic intellectualist view of virtue, this analysis has a strikingly physicalist emphasis. Similarly, where Zeno had called a mental impression (*phantasia*) a 'printing' in the soul, Cleanthes was criticized by his successor Chrysippus for treating this as a literal imprint, as if in wax.

Cleanthes' deeply religious temperament is evident from his *Hymn to Zeus*. There, uniquely among Stoics as far as we know, he enhances god's majesty by absolving him of willing the actions of the bad. Another symptom is his outrage at the contemporary astronomer Aristarchus, who alone in antiquity suggested that the earth might orbit the sun rather than vice versa, while revolving on its own axis. Cleanthes proposed that he be prosecuted for impiety, because his theory 'moved the world's hearth'. Yet he is also the author of some surprisingly rationalistic explanations of the origin of religion (Cicero, *On the Nature of the Gods* II 13-15).

Cleanthes' interest in logic is attested by the solution he provided to the Master Argument (see Diodorus Cronus §5), which was being used to argue for the necessity of the future. He responded by rejecting its premise 'Every past truth is necessary', perhaps on the ground that present and future events determine the truth-value of past predictions.

Clement of Alexandria (AD 150-215)

Clement of Alexandria, a Christian Platonist, came to conversion through philosophy. In a series of allusive writings he presented a Hellenized Christianity along with the philosophical syncretism of his age: Stoic ethics, Aristotelian logic and especially Platonic metaphysics. Just as Paul saw the Hebrew prophets and law as a preparation for the Gospel, Clement saw Christianity as making possible a confluence of Plato and the Old Testament, both offering anticipations of Jesus' teaching. Clement's fusion of Platonism and Christianity vehemently opposed the dualism and determinism of gnostic theosophy, and stressed free choice and responsibility as fundamental to moral values. Central to his writing is the vindication of faith as the foundation for growth in religious knowledge by philosophical contemplation and biblical study.

Clement's principal works are *Protreptikos (Exhortation to Conversion)* attacking polytheism, *Paidagogos (Moral Tutor)* on etiquette and Christian ethics, and above all the *Stromateis (Miscellany)*, left incomplete. The eighth and last book of *Stromateis*, Clement's commonplace work on logic and epistemology, was not part of the original plan. He intended to make the third work in his trilogy a systematic statement of religious philosophy entitled *Didaskalos (Teacher)*, but wisely, since it would have been controversial, he never wrote it.

The *Stromateis* touches elusively on profound issues but then changes the subject. The reader is invited to participate in the quest for religious truth, granted to those who strenuously search but also receive divine help. If one had to make a choice between eternal salvation and continuing growth in the knowledge of God, one would certainly choose the latter (a saying plagiarized without acknowledgement by G.E. Lessing in *Duplik*).

Platonic language appears in Clement's theme of the mysteriousness of faith in God. Echoes of Plato's seventh letter are heard in his diffidence about putting advanced theology into writing, and the third book of the *Republic* provides his model for attacks on the clever and conceited who scorn such topics.

Clement's objective is to defend educated Christians who see no reason to jettison good philosophy merely because they have renounced the world, the flesh and the devil. Many in the Church were suspicious of philosophers because of the appeal made to them by gnostic sects claiming to offer a higher understanding (*gnosis*). The 'orthodox' (Clement uses the word with an ironical touch) were confident that faith alone sufficed for salvation. Some asserted (following Enoch 16:3) that philosophy was the invention of the devil, transmitted to humanity through the fallen angels' mating with women. Clement noticed that even this negative notion implicitly conceded that in philosophy, perhaps in confused form, there was heavenly truth. He was sure that Plato on God's transcendence, on the aspiration that the soul be 'as like God as possible' and on the goal of the vision of God (as in *Phaedrus*) was so close to Christian faith as to be virtually indistinguishable. The Stoics, on the therapy of the emotions and on the absolutes of the moral life, were similarly stating what he knew to be true. Here Clement owed much to Philo of Alexandria, especially for the thesis that philosophy prepares the mind for theology just as the liberal arts prepare it for philosophy.

How the philosophers succeeded in getting so much right was a question with more than one possible answer. Clement's main answer is that all human beings, being made in God's image, possess a 'shared mind', a 'natural conception' as the Stoics had put it, and so have a universal intuition for God and for virtue and righteousness. The philosophers' ability to 'reflect the truth' may therefore be ascribed to the exercise of natural endowment. Moreover, there can be special inspiration imparted to selected individuals; that this inspiration is Christian in nature is evident from Jesus' parable of the sower.

Philo and Numenius of Apamea had earlier supposed that Plato had been able to get so much right because of his studies in the writings of Moses, who could be shown by chronographers to have lived centuries earlier. Clement develops at length the theme of Greek plagiarism from barbarian traditions, inverting an argument deployed against Christianity by the pagan Platonist Celsus, whose work *Alethes Logos (The True Account)* Clement probably knew. Celsus also thought the oldest and most venerable religious tradition was to be found among primeval barbarian peoples uncorrupted by civilization. Clement was not therefore implausible to his contemporaries in suggesting that classical philosophy was dependent on older, non-Greek tradition for religious truth; and such a lack of religious originality in Plato or Pythagoras was, for him, no demerit.

The nature of faith was a problem never far from the centre of Clement's stage. It was under attack on one side from gnostics who scorned simple catechetical teaching (see Gnosticism); on the other side, educated pagans thought the Christian exhortation to 'believe' denied rational investigation and asked for mere submission to authority. Clement drily remarked that the latter method was a famous principle of no less a figure than Pythagoras. Religious faith he saw as related to natural assent. We assent, without a full prior inquiry, to the presuppositions of rational demonstration. We use the term 'faith' (*pistis*) for the state of satisfied conviction at the conclusion of a sound argument, or for the immediacy of assent to what our senses perceive. The word also contains some element of the commitment of loyalty to a cause or a person. In Christianity, faith is the necessary precondition of advance in the knowledge and love of God through meditation on the inner, symbolic, meaning of Scripture, linked to contemplation of higher things. Thereby the soul may be gradually freed from the distractions of passion and enabled to rise to the mystical vision of God.

Much technical Stoic and some Aristotelian language enters Clement's description of the conflict between reason and emotion. To live according to nature is to obey the Creator-Logos, Reason for all things, who for Clement is known in Christ and who is able to bring power to moderate the passions and, at the highest level of ascetic contemplation, suppress them. Passionlessness (*apatheia*) is synonymous with Plato's 'likeness to God', and with the perfection of which Jesus spoke in the Sermon on the Mount.

Cleomedes (*c*. 2nd century AD)

Cleomedes was the author of On the Heavens, a Greek treatise on elementary astronomy surviving from a larger exposition of Stoic philosophy. Its account of measurements of the earth, and its applications of Stoic epistemology and philosophy of science, make it important evidence on poorly documented subjects.

Since Cleomedes refers to Posidonius (*c*.135-*c*.50 BC), and conducts polemics against Peripatetics and Epicureans, he could not have been active much later than AD 200. *On the Heavens*, his presentation of elementary astronomy, is part of a larger exposition to which he himself alludes (see I 1.7, and I 1.94-5). Book I deals with celestial and terrestrial zones, seasonal and climatic differences (I 1-4), the sphericity and centrality of the earth (I 5 and 6) and the earth's transparency in celestial observations (I 8). The account in I 7 of Posidonius' and Eratosthenes' measurements of the size of the earth is indispensable evidence for historians of science. The subjects of book II 1-3 are the size of the heavenly bodies, and in particular the Epicurean view that they are no larger than they appear, and lunar theory (II 4-6). A brief appendix (II 7) deals with planetary latitudes, elongations and periods. The work is non-technical, eschews discussion of the complexities of planetary motion and presents material in the stylized fashion typical of ancient elementary pedagogy.

In Byzantium and Renaissance Europe *On the Heavens* was exclusively used as a textbook of elementary astronomy. In the late nineteenth and early twentieth centuries scholars mined it for specific doctrines of Posidonius. But it is Posidonius' philosophy of science that is of the greatest significance for Cleomedes (see Posidonius §6). Posidonius (fr. 18) had defined astronomy as a science subordinate to physical theory, and as employing the ancillary sciences of mathematics and geometry. Cleomedes' work may not precisely embody this programme, but it does fall within its general orbit. Thus it specifies the role of assumptions from physics and geometry in calculations of the size of the earth, sun and moon (I 7; II 1.282, 304-5). Also, the treatise opens by defining, with detailed supporting arguments, the physical context for spherical astronomy as the standard Stoic cosmology of a finite world in infinite void. Elsewhere the theories of the Stoic continuum play a much larger role than physical theory normally would in astronomical handbooks (see for example I 5.6-9, 126-38; I 6.40-3; I 8.79-99; II 4-). The epistemological problems raised by astronomical observations, to which Posidonius (fr. 18) also alludes, are reflected in references to the Stoic theory of the criterion of truth (I 5.1-6; II 1.1-4), and in the lengthy polemic in book II 1 against the Epicurean claim that the sun is no larger than it appears.

It may be unfortunate that Cleomedes' Stoicism is embedded in a survey of elementary astronomy, but in the absence of his other works, *On the Heavens* at least shows that the Stoicism of late antiquity was not, as has been traditionally thought, exclusively preoccupied with prescriptive ethics.

Cockburn, Catharine (1679-1749)

Catharine Cockburn (Catharine Trotter) was a British moral philosopher who turned to philosophy after a successful career as one of the first woman playwrights. She wrote no substantial systematic treatise of her own, but intervened ably and anonymously in philosophical and theological debates of her day, in particular the debate on ethical rationalism triggered by Samuel Clarke's 1704-5 Boyle lectures. Her adversaries included Thomas Rutherforth, William Warburton, Isaac Watts, Francis Hutcheson and Lord Shaftesbury. Her most famous contribution to the philosophy of her time was her able 1702 defence of Locke's Essay Concerning Human Understanding. Her letters, published posthumously, discuss a range of philosophical topics.

Born Catharine Trotter, in London of Scottish parentage, Cockburn appears to have been largely self-taught in philosophy. She was linked to circles around, first, the playwright William Congreve, and later Gilbert Burnet, Bishop of Salisbury. The latter may have been instrumental in persuading her to give up writing plays in favour of philosophy. After her marriage in 1708 to the Scottish clergyman Patrick Cockburn, the adverse pressures of rearing a family in reduced financial circumstances combined with deteriorating eyesight to hamper her pursuit of philosophy.

Throughout her writings Cockburn is consistent and nondogmatic in her philosophical position. Among the topics she discusses are necessary existence, infinite space, the idea of substance and the nature of spirit, but her main focus is on ethical questions, in particular the nature of virtue and of moral obligation. Opposing the ethical relativism of Hobbes, she argues that morality is neither arbitrary nor conventional in foundation (see Hobbes, T. §5). Against latter-day would-be defenders of morality, she denies that moral virtues exist in the abstract and that the obligation to virtue is founded in innate moral sense. Nor does moral obligation depend on externally imposed sanctions. Rather, moral obligation and the principles of moral conduct can be understood from the 'reason, nature and fitness of things' (1751a, vol. 2: 44). Human beings are rational and social beings, so for human beings to act in accordance with their own nature is to act rationally and for the good of all. By the exercise of reason we arrive at a knowledge of the principles of right and wrong from ideas of sensation and reflection. Having thus acquired a concept of goodness, we deduce that God is good and deserves our obedience, and that it is most fit for a reasonable being to act in conformity with God's moral perfections.

The outlines of the philosophical position from which Cockburn defended Clarke are already evident in her defence of Locke in which she wrote 'I know no philosopher before him that has fixed morality upon so solid a foundation' (1702: 48). It is to her credit that, although she did not agree with Locke in all particulars, she defended him against misunderstandings and misreadings that imputed to him scepticism or deism, exposing the inconsistencies and fallacious arguments of his opponents: as she reminded his critics, 'the question is not what Mr. Locke thinks, but what may be proved upon his principles' (1702: 60). She rallied twice more to Locke's defence in *A Letter* (1826) and Vindication (1751b), defending his philosophy from charges that it undermined Christian orthodoxy.

Catherine Cockburn was recognized as an astute mind by her contemporaries, among them Locke, who gratefully acknowledged her defence of his philosophy. Leibniz, too, praised her writings, and she was dubbed 'Sappho Ecossoise' by Leibniz's patron, Sophie Charlotte of Hanover.

Coercion

Coercion (also called 'duress') is one of the basic exculpating excuses both in morality and in some systems of criminal law. Unlike various kinds of direct compulsion that give a victim no choice, a coercee is left with a choice, albeit a very unappealing one. They can do what is demanded, or can refuse, opting instead for the consequences, with which they are threatened. Sometimes courts find that the coercive threat that led the defendant to act as they did was objectively resistible by any person of reasonable fortitude, especially when the defendant's conduct was gravely harmful to others or to the state.

A proposal is an offer when it projects for the recipient's consideration a prospect that is welcome in itself, and not harmful or unwelcome beyond what would happen in the normal course of events. Coercive offers, according to some writers, are those that force a specific choice from the victim while actually enhancing their freedom. Some argue, however, that genuine coercion requires the active and deliberate creation of a vulnerability, and not mere opportunistic exploitation of a vulnerability discovered fortuitously.

1 Coercion and compulsion

Coercion is a technique for forcing people to act as the coercer wants them to act, and presumably contrary to their own preferences. It usually employs a threat of some dire consequence if the actor does not do what the coercer demands, although it is controversial whether a non-threatening offer might in some contexts be coercive (see §2). There is a contrast between coercion, in which the victim can choose one or the other of the two alternatives allowed by the coercer (for example, 'your money or your life'), and what we might call compulsion, in which the victim has no choice at all, as for example when the victim is knocked unconscious and dragged away. In compulsion, options are closed by physical force, making alternatives to what the coercer demands physically impossible. In contrast, coercion does not destroy the preferred alternative as much as destroy its appeal by increasing its cost. The cost is the alternative specified in the coercer's threat.

2 Threats and offers

If such things as 'coercive offers' exist they must not, by definition, be a species of threat, but rather be in essential contrast to the more typical instances of coercion which involve a demand enforced by a threat. Coercive offers would also be in contrast to the more familiar noncoercive inducement; attractive prospects which function as enticements that one 'cannot resist'. With few exceptions, philosophers have held that allegedly 'irresistible' attractiveness does not negate voluntariness or excuse the attracted party from responsibility.

The common genus of which threats and offers are species is that of preference-affecting proposals - those proposals not likely to be received with perfect indifference. To begin with, an offer is a proposal to contribute to a person something that they want or find welcome, something they would prefer having to not having. A threat, on the other hand, is a proposal to inflict something they would not welcome. But, threats and offers are more than 'proposals.' They also contain a reciprocation condition; a 'demand' in the case of threats, and a 'request' in the case of offers. These elements amount to the coercer's *quid pro quo*: 'what is in it for them'. In the case of coercive threats, at least, far more is in it for them than for the other party. This way of speaking makes it clear that credible threats in support of demands are a kind of contractual transaction, but a transaction so lopsided as to be unconscionable, involuntary on one side, and legally invalid.

One kind of preference-affecting proposal is a demand backed by a threat; another is a request backed by an inducement. Both of these can be construed as typically biconditional in form: the action that *A* requests or demands from *B* is taken to be both a necessary and a sufficient condition of *A*'s reciprocation: 'I will do *x* to (or for) you *if and only if* you will do *y* for me'. *A*'s offer of $11,000 for *B*'s car thus translates:

(1) If you give me your car, I will give you $11,000.
(2) If you do not give me your car, I will not give you $11,000.

The first preference-affecting proposal (1) - 'I will give you $11,000' - is obviously an offer. The second - 'I will not give you $11,000' - is not an offer, but neither is it a threat. 'I will not give you $11,000' would count as a threat only if the speaker paid that amount regularly and was now proposing to withhold it, thus disappointing the

other party’s natural expectation. Since the proposal is part offer and part neither offer nor threat, it is an offer overall.

Such an example is an easy case. It would be more difficult if it were unclear what the ‘normal course of events’ was, or what is in the circumstances a ‘reasonable expectation’. An important element of the analysis then would be some proposed ‘norms of expectability’. Some writers employ for this purpose a kind of statistical test while others employ a test of moral requiredness (Nozick 1969). Suppose the consequent clause in the second biconditional (2) is something like: ‘I will not pull you out of the lake in which you are about to drown’ (unless you promise to sign over all your worldly goods to me). Such a proposal violates a moral norm. We not only expect most people in such circumstances to attempt easy rescue (statistical norm); our morality *requires* it (moral norm). Thus the proposal not to rescue would be a threatened deviation both from statistical and from moral norms. And when the projected behaviour deviates from one of these norms but not the other, it can be sufficient to classify it as a threat. In summary, if *A*’s projected consequences of *B*’s failure to do *y* are worse (or less welcome) than they would be in the normal and expected course of events (where ‘expected’ straddles ‘predicted’ and ‘morally required’), then *A*’s proposal is a threat. If it correctly portrays those consequences as improvements, it is an offer.

3 Coercive and noncoercive proposals

Various examples, actual and hypothetical, have convinced some writers that there are such things as coercive offers. One rather standard example is that of the ‘lecherous millionaire’: *B*’s child will die unless the child receives expensive surgery. *A*, a millionaire, proposes to pay for the surgery if, but only if, *B* will agree to become his mistress (Wertheimer 1987: 229). The millionaire’s proposal, which does not project any harm beyond what would happen without his gratuitous intervention, is clearly an offer; an ‘illicit offer’, but an offer none the less. The controversy over this example has been mainly over whether the offer is coercive or not. On the one side, it has been argued that the example, at least from *B*’s point of view, is coercive in just the sense in which the standard gunman’s threat is coercive (Feinberg 1986). In both examples, the powerful wrongdoer (*A*) uses superior advantages (weapons or money) to manipulate *B*’s options so that *B* has ‘no choice’ but to do what *A* wants. In either case, the option seen from the victim’s point of view is: ‘Sleep with me or your baby dies’.

On the other side, it is frequently argued that it is misleading to label as ‘coercion’ a proposal the effect of which is to create a net *increase* in a person’s options, giving them a valued choice not previously possible (Zimmerman 1981). Thus *B* has been given an option she did not have before, without losing any options that she did have before, so that in a sense her freedom has been increased. Yet to some the suggestion that a coercive proposal could be freedom-enhancing is intolerably paradoxical.

4 Coercion and exploitation

A different solution is proposed by David Zimmerman (1981), who employs a critical distinction between coercion, understood as necessarily restrictive of freedom, and exploitation, understood as not necessarily coercive. In the lecherous millionaire example, *A* is an opportunist who happens to chance upon a vulnerable party, but who played no role himself in creating her vulnerability. In Zimmerman’s terms, that makes *A* an exploiter. For him to be a genuine coercer, it must be the case that he deliberately created the situation in which *B* is helpless. Zimmerman illustrates the distinction between exploitative offers that are, and those that are not coercive, with the following example: *A* kidnaps *B*, brings him to the island where *A*’s factory is located, and abandons him on the beach. All the jobs in *A*’s factory are considerably worse than those available on the mainland. The next day *A* approaches *B* with the proposal ‘Take a job in my factory and I won’t let you starve’.

This example is a genuine coercive offer, according to Zimmerman, but if there were two factories on the island, and the owner of the second learns of *B*’s plight and rushes to the beach before *A* can get there in order to make the same kind of offer to the kidnapped worker, then *A*’s offer is merely opportunistic exploitation: ‘Coercing goes beyond exploiting, however objectionable the latter may be’ (Zimmerman 1981: 122). The effect on the victim appears to be coercive whether the exploiter deliberately created the vulnerability or only took advantage of it opportunistically. ‘Work or starve’ is as coercive in effect as ‘Sleep with me or your baby dies’. However, in the example that Zimmerman uses, *A* inflicts a kind of double blow on *B*, first by undermining *B*’s freedom (the act of kidnapping) and then by taking advantage of his undermined state with a ‘coercive offer’. The lecherous

millionaire, in contrast, was a mere opportunist. Whilst his behaviour may be viewed as morally reprehensible, it can be argued that his unsavoury conduct did not violate the vulnerable party's right; nor did it threaten any harm to *B* beyond what she could expect to occur anyway in the normal course of events.

Cognition, infant

In the past thirty years developmental psychologists have developed techniques for investigating the cognitive resources of infants. These techniques show that an infant's initial representation of the world is richer and more abstract than traditional empiricists supposed. For instance, infants seem to have at least some understanding of distance, of the continued existence of objects which are out of sight, and of the mental states of others. Such results have led philosophers to reconsider the idea - to be found in Plato - that there may be innate constraints on the way we view the world, and to examine the extent to which innate 'knowledge' may be revised as a result of learning.

How do we ask prelinguistic infants what they know? Infants' behaviour may initially look random and confused, but with closer observation, and particularly with the aid of videotape, we have discovered that it is quite systematic and structured. Very young infants show distinct emotional expressions. They act on objects in distinct and appropriate ways. Infants imitate the actions of others. We can use these patterns of action and emotion to test experimentally how infants behave when we present them with new events.

But we can also use other techniques that do not depend on spontaneous behaviour. Infants show characteristic shifts of visual attention and these shifts have been widely used to assess infant knowledge. An infant is first shown some event over a period of time. Infants typically look attentively at the event at first and then their attention declines, a process called habituation. We can then show the infant a new event. If the infants think the new event is different from the earlier event their attention will return; they will, once again, look attentively, a process called *dis*habituation. But if they think the new event is only a minor variant of the original event it will not capture their attention.

Philosophers have puzzled over the gap between our ordinary conception of the physical world as three-dimensional enduring objects moving in space and the information that arrives at our senses. For example, one classic question is how we infer a three-dimensional world from a two-dimensional retinal image (see Empiricism; Phenomenalism; Vision). Newborn infants seem to have at least some understanding of distance. Even very young infants will extend their arms towards objects within reach, but not out of reach. Similarly, newborn infants show size constancy. They recognize that an object that has moved away from them is still the same object, in spite of the fact that the retinal image is smaller.

A similar puzzle about object knowledge is the Molyneux problem (see Molyneux problem). How do we link information about the same object that comes from different sensory modalities? Intermodal mapping is found in very young infants. Newborn infants imitate visually perceived facial gestures, although they cannot see their own faces, suggesting a mapping between tactile and visual experience. Similarly, in one experiment, infants sucked on either a bumpy or smooth object without ever being allowed to see it. Then they saw a visual image of either a bumpy or smooth object without touching it. Infants consistently looked more at the visual image that matched their previous tactile experience. Infants show a similar appreciation of the congruence between the temporal pattern of a sequence of noises and a sequence of flashes.

Yet another question is how we understand that objects endure even when they move out of sight. Infants appear to make some predictions about the possible movements of visible objects. Even very young infants reach for objects in the dark, suggesting that they can also represent objects that are out of sight for at least a brief time. However, infants will not search for objects that are hidden behind screens or under cloths until they are about 9 months old. This is in spite of the fact that they have the motor capacity to search under screens, and can remember seeing the objects being hidden. Their actions suggest that they believe the object no longer exists.

In contrast, some visual attention experiments suggest that young infants can draw inferences about objects behind screens. For example, we can show 5-month-old infants a screen that folds backwards to a flat position until they habituate to that event. Then we can show them an object in the path of the folding screen. The screen either folds flat (apparently going through the space that should have been occupied by the object), or the screen stops when it reaches the appropriate angle, as if blocked by the hidden object. Infants look more at the first event than the second, in spite of the fact that the first event is actually more superficially similar to the habituating event. In the

case of distance and intermodal matching, the action and attention experiments give similar results. However, in this case there appears to be a discrepancy between the findings from studies of action and of attention. Children apparently demonstrate one set of beliefs when they act on objects and another contradictory set of beliefs when they look at objects. There is an ongoing debate about whether the attention-effects imply that infants understand enduring objects.

Another classic problem is how we infer that others have mental states like our own, given only the evidence of their behaviour (see Other minds). Very young infants act in ways that seem coordinated with the actions and emotions of others, and at around 9 months show signs of understanding that mental states are directed at objects. At this point infants begin to point at objects and to follow the gaze and pointings of others (see Mind, child's theory of).

What philosophical conclusions can we draw from these empirical results? One theoretical possibility might be the sort of strong nativism advocated in Plato's *Meno*, in which Socrates wonders how it is that we have abstract and complex representations of the world, when the evidence of our senses is so limited and concrete? He answers the question by conducting a psychological experiment on a child, Meno's slave boy, testing whether he has the abstract representations in question (*Meno* 82b-86b). When it turns out that he does, Socrates concludes that the representations are innate, a view later echoed by Descartes and Kant. In its modern version, the nativist view suggests that there are strong and unchanging innate constraints on the way we view the world, a kind of 'core knowledge' (see Innate knowledge; Nativism). On an alternative view, the ability of infants to learn and change their beliefs is as impressive as their innate endowment. On this view infants begin with rich innate representations of the world, but those representations are subject to often quite radical revision as the infant learns more about the world. On this view, the infant is like a scientist who constructs and revises theories, and the innate representations are initial theories (see Learning). On either view, infants are an important and often neglected source of information about basic epistemological questions.

Cognitive architecture

Cognitive architecture involves the properties of mental structures and mental mechanisms that do not vary when people have different goals, beliefs, precepts or other cognitive states. A serious computational theory of mind (CTM) requires that the architecture be constrained independently of such states. One consequence of taking the distinction between architecture and representation-governed process seriously is that it provides a reply to those who are sceptical about the role of rules in cognition, on the grounds that following rules leads to an infinite regress: in CTM, rules are executed by the causal structure of the architecture, and hence do not require further rules for following rules.

The notion of cognitive architecture in the context of the computational theory of mind (CTM) comes directly from the notion of computer architecture, which refers to the relatively fixed set of computational resources available to a programmer in designing a program for a given computer system. Among other properties, this includes the type of memory that the computer has, the way it encodes information (the system of symbolic codes or language it uses), the basic operations that are available, and the constraints on the application of these operations (as in serial v. parallel sequencing). The architecture is a functional characterization of the computer system on which the program runs (see Mind, computational theories of).

It is important to bear in mind that computer architecture reflects the physical properties or 'hardware' only indirectly, since the architecture visible to the programmer might itself be simulated in software or firmware. For this reason it is sometimes referred to as the 'functional architecture' or even as the 'architecture of the virtual machine'. Someone writing a program in, say, LISP or C, has available the resources (operations, datastructures and programming constraints) of those languages and is not concerned with their physical instantiations: LISP or C in that case*is* the architecture of the relevant virtual machine.

In theories of cognition, the notion of architecture is particularly important because it represents the dividing line between cognitive and non-cognitive aspects of a model. In CTM, mental processes are modelled as computer programs, but the process of executing these programs itself lies outside the domain of CTM. What makes the computer model run, or generate token instances of behaviour, is the causal structure of the underlying computational mechanism, the computational architecture.

The architecture of computational models was often taken for granted in modelling cognitive processes. In the 1950s, information-processing models were typically expressed in terms of whatever architecture was available or seemed intuitively reasonable - usually a so-called 'von Neumann' architecture which uses a serial fetch-execute computational regime and location-addressable register memory. But in more recent years, under the influence of Simon and Newell's literal interpretation of programs-as-theories (see Simon and Newell 1964; developed more fully in Newell 1990), it became clear that the assumptions one made about the underlying architecture strongly influenced which programs it could implement (not which functions it could compute, since with suitable external memory it could compute any computable function) and hence constituted a strong claim about the nature of mind.

Mapping out the cognitive architecture in detail is important if the CTM is to provide a literal scientific hypothesis about the causes of cognitive behaviour. Programs can only be individuated relative to an architecture. According to the way in which computer scientists and cognitive scientists individuate programs, two different architectures cannot execute the same program, although the universality of such machines guarantees that (subject to memory requirements) they can compute the same function. The kind of 'strong equivalence' of computational models with mental processes that many cognitive scientists demand is not achieved just by providing a detailed characterization of the process in the form of a program. Because the form of such a program depends on the architecture on which it runs, the theory must specify an independently motivated architecture, including a specification of the representational system it uses. In such a fully articulated model the individual operations - as well as the symbolic expressions they operate over - the sequencing discipline that is imposed on the program execution, the memory constraints that it must adhere to, and so on, all constitute empirical claims. Only when one has independently specified both the architecture and the representations can one's computational model lay claims to being 'strongly equivalent' to the cognitive process being modelled (see Pylyshyn 1984).

In recent years there has been a great deal of debate about which class of architecture is the right one for modelling cognition. In particular there have been proposals that the class of computational architectures that operate over syntactic strings, as in the Turing machine or in proof theory, are inappropriate for modelling psychological processes (see Turing machines; Proof theory). Instead, some people have proposed so-called 'connectionist' or 'neural net' architectures, consisting of a network of simple threshold elements that compute certain functions (the precise class being unknown) by passing activation among the elements over weighted links (see Connectionism). Such networks, it is claimed, compute without reading or writing symbolic expressions. The debate raises the philosophic issue of whether mind can or should be modelled as a syntactic engine, computing in a 'language of thought', as is generally assumed in the CTM (see Fodor and Pylyshin 1988; Language of thought).

Distinguishing architecture and representations (including representations of processes in terms of programs which run on that architecture) is important to the philosopher for a number of reasons (see Pylyshyn 1996). For one, it represents an attempt to understand the nature of the relatively fixed mental structures that instantiate psychological processes: the basic cognitive *capacities* of the mind within which representation-governed processes are instantiated. Some of these structures are likely to be universal and perhaps even innate (we put aside for now the issue of how architecture changes, except to note that it does not change in response to new knowledge - by definition it is not 'cognitively penetrable').

Recognizing the role of architecture also helps to resolve a problem about rule following raised by Wittgenstein (1953): how is a system to know how to follow a rule? If by using another rule, this invites an infinite regress (see Wittgenstein, L. §10). In CTM the regress does not arise because the architecture executes the rules and it does not do this by using rule-following rules, but, instead, by virtue of its causal structure. In a computer we do not have to have algorithms for executing algorithms; instead the physical instantiation of the algorithm in the machine, together with the structure of the machine, simply causes the behaviour to unfold. The relevant abstract description of these causal-structural properties constitutes a description of the architecture of the system.

Cognitive development

Psychological research of the last two decades has produced a surge of surprising results regarding cognitive development in children that has challenged a number of traditional philosophical assumptions about the nature of knowledge. The developing cognitive system seems organized in terms of specific domains, rather than as a general, all-purpose processor to which traditional empiricism was committed. Children's conceptual development is often guided by highly abstract principles and parameters that are present in a child's mind long before concrete details of a domain are encountered. Moreover, the data seem to indicate that development consists predominantly of gradual conceptual enrichment over time, rather than radical change.

Research in cognitive development addresses the nature of thought and perception, focusing specifically on the origins of cognition, and its changes over time. Thus, it addresses such questions as what sorts of innate expectations infants possess about the kinds of things to be learned; whether development is continuous or stage-like in nature; whether it proceeds from more concrete to more abstract forms of thought; and finally, the nature of cognition itself as either a global and general learning system, or a set of more specialized and separable domain-specific systems (see Modularity of mind).

The emergence of the experimental study of cognitive development in the twentieth century is largely attributed to a few key figures, most notably Jean Piaget, Lev Vygotskii and Heinz Werner. All three favoured stage-like transitions in cognitive development that had sweeping influences across all domains of thought. Although significant portions of their theories are no longer widely believed, the phenomena they uncovered still remain the focus of most contemporary experimental work: knowledge of, for example, arithmetic, spatial layout, physical object mechanics and social interaction.

The last two decades of empirical research on these phenomena have produced a surge of new results that support increasingly strong claims about the nature of cognitive development. Contrary to the associationist assumptions of traditional empiricism, it seems to be guided by highly abstract principles and parameters about specific domains of inquiry - for example, language, causal relations among material objects, biology, intentional psychology - long before the domain is actually encountered. Indeed, along the lines of traditional Rationalism, many of them are arguably innate (see Empiricism; Nativism; Rationalism).

Much of this recent work has been influenced by the revolution in linguistics brought about by Noam Chomsky. Chomsky provided convincing evidence that, in the normal human environment, language is unlearnable unless the learner has specific sets of innate expectations about the nature of grammar. For example, children make systematic errors they have never heard spoken, and use syntactic rules that they have never been taught. Although the nature of this language-specific endowment is still actively debated, the vast majority of language acquisition researchers now acknowledge the need for an a innate set of predetermined expectations about linguistic structure (see Language, innateness of).

Following this proposal in linguistics, many psychologists now argue that children possess innate or early-developing predispositions that guide the development of their understanding of other types of knowledge domains, such as the mechanics of physical objects (see Cognition, infant) and human social behaviour (see Mind, child's theory of). As with language, this domain-specific approach has been proposed to explain both children's impressive cognitive abilities, and their puzzling defects. For example, young infants clearly see objects as solid three-dimensional things (solidity) that move in predictable ways (continuity), but fail to understand gravity, even though evidence for all three is roughly equally present (and important) in the environment (Spelke *et al.* 1992). Infants seem to have a 'theory' of physical objects that ignores gravity until much later in development. This theory may not be as elaborate or extensive as that used by adults, but clearly it guides children's developing understanding of the world in ways similar to adults'.

At least by the age of 3 or 4, children also seem to have a special 'teleological' framework for interpreting some phenomena. Preschool children are more prone to ask such questions as 'What's this for?' when asking about a property of a living kind than of a non-living natural kind, such as a rock, about which they are more likely to ask merely 'What is that?', or 'What is that *P* [property]?', without any presumption that it serves any purpose. They

seem to recognize that the features of living kinds are interconnected and designed in some manner to be causally linked in a way not true of non-living natural kinds. This bias towards teleological explanation may be a fundamental component of conceptual development (Keil 1995). Moreover, when told that human beings possess specific biological properties such as eating, sleeping and having hearts, preschool children will show highly structured patterns of generalization of these properties to living as opposed to non-living kinds (Carey 1985).

It is important to note that these explanatory frameworks go beyond mere associative principles. For example, although being curved is a property equally associated with both bananas and boomerangs, it is causal and central only in the latter case. A straight banana is clearly still a banana, but a straight boomerang is a stick (see Medin and Shobin 1988; Behaviourism, methodological and scientific; Learning §2).

Contrary to earlier claims, recent research also suggests that development consists predominantly of gradual conceptual enrichment over time, rather than radical change. Rather than undergoing a series of cognitive metamorphoses as Piaget supposed, the infant's world contains many parameters of understanding that continue to play a role across development, and into the conceptual systems of adults. For example, 6-month-olds understand that objects continue to exist even when they cannot see them (Diamond 1991), and infants have a surprising understanding of numerosity and some aspects of counting (Gallistel and Gelman 1992).

Research on cognitive development is currently being conducted in a manner that crosses traditional research boundaries and more closely follows the spirit of cognitive science. Carey (1991) has found striking parallels between conceptual development in children and conceptual developments in the history of science. Anthropologists find exciting commonalities in what people in all cultures regard as fundamental categories such as living kinds (Atran 1995). The relevance of linguistics to conceptual development is clearly apparent. Philosophical contributions to such efforts come from many directions, including logic and the nature of inductive learning devices (see Inductive inference), conceptual change in science (see Concepts), the formal nature of reasoning (see Common-sense reasoning, theories of), clarifying relations between metaphysics and epistemology, and how the nature of thought might be revealed through language (see Language, philosophy of).

Cognitive pluralism

Descriptive cognitive pluralism claims that different people, or people in different cultures, go about the business of reasoning (that is, forming and revising beliefs) in significantly different ways. If descriptive cognitive pluralism is true, it lends considerable urgency to the venerable philosophical problem of deciding which strategies of belief formation and revision we ourselves should use. Normative cognitive pluralism claims that various quite different systems of reasoning may all be equally good. Epistemic relativism, which claims that different strategies of reasoning are best for different people, is a species of normative cognitive pluralism. Evaluative-concept pluralism claims that different people in different cultures use very different concepts of cognitive evaluation. Their notions of rationality and justification (or the closest equivalents in their culture) are quite different from ours. If this is right, it poses a prima facie *challenge to a central strategy in analytic epistemology which tries to arbitrate between different systems of reasoning by determining which system best comports with our own concepts of epistemic evaluation.*

1 Descriptive pluralism

‘Cognitive pluralism’ might be used to label at least three distinct though related claims. One of these, which I call ‘descriptive cognitive pluralism’, has been much debated in anthropology, comparative psychology and the history of science. Descriptive pluralism maintains that different people go about the business of cognition - the forming and revising of beliefs and other cognitive states - in significantly different ways. For example, it has been urged that people in certain pre-literate societies think or reason very differently from the way modern, Western, scientifically educated people do. Closer to home, it has been suggested that different individuals or groups in our own society (men versus women, artists versus scientists, well-educated versus poorly educated) form beliefs and solve cognitive problems in markedly different ways - ways that indicate differences in underlying cognitive processes (see Feminist epistemology §4).

The denial of descriptive cognitive pluralism is descriptive monism, the thesis that all people exploit more or less the same cognitive processes. The distinction between descriptive monism and descriptive pluralism is best viewed not as a hard and fast one, but as a matter of degree. No one would deny that people differ from one another to some extent in the speed and cleverness of their inferences; nor would it be denied that in attempting to solve cognitive problems, different people try different strategies first. But if these are the only sorts of cognitive differences to be found among people, descriptive monism will be vindicated. If, on the other hand, it should turn out that different people, different groups or different cultures use radically different ‘psycho-logics’ - that the revising and updating of their cognitive states is governed by substantially different principles - pluralism will have a firm foot in the door. The more radical the differences, the further we will be towards the pluralistic end of the spectrum.

If descriptive cognitive pluralism turns out to be true, it is possible that some of the diversity in reasoning strategies may be due to genetic differences among individuals or groups. But it might also be the case that some of the diversity, or all of it, is attributable to environmental variables that differ in important ways from one culture to another. Some of the rules of reasoning that people internalize and use, or all of them, may be analogous to the grammatical rules that subserve the production and comprehension of sentences in natural languages. The possibility that there is a fair amount of acquired diversity in human cognitive processes, and that patterns of reasoning or cognitive processing are to a substantial degree moulded by cultural influences, adds a certain urgency to one of the more venerable problems of epistemology. For if there are lots of different ways in which the human mind/brain can go about ordering and re-ordering its beliefs and other cognitive states, if different cultures could or do go about the business of reasoning in very different ways, it becomes quite pressing to ask which of these ways should we use and which cognitive processes are the good ones? Here the analogy with grammatical rules breaks down in an illuminating way. Most of us are inclined to think that one language is as good as another. The one you should use is the one spoken and understood by the people around you. By contrast, most of us are not inclined to accept this sort of thorough-going relativism about cognitive processes. If pre-literate tribes or pre-modern scientists or members of a contemporary sub-culture or our own distant descendants think in ways that are quite different from the ways we think, few of us would be inclined to suggest that all of these ways are equally good. Some ways of going about the business of belief revision are better than others. But just what is it

that makes one system of cognitive processes better than another, and how are we to tell which system of reasoning is best? These are among the most basic and the most disquieting questions that epistemology tries to answer.

2 Normative pluralism

Normative cognitive pluralism is not a claim about the cognitive processes people do use; rather it is a claim about good cognitive processes - those that people ought to use. It asserts that there is no unique system of cognitive processes that people should use, because various systems that are very different from each other may all be equally good. The distinction between normative pluralism and normative monism, like the parallel distinction between descriptive notions, is best viewed as a matter of degree, with the monist end of the spectrum urging that all normatively sanctioned systems of cognitive processing are minor variations of one another. The more substantial the differences among normatively sanctioned systems, the further we move in the direction of pluralism. Epistemic relativism is a species of normative cognitive pluralism. An account of what makes a system of reasoning a good one is relativistic if it entails that different systems are good for different people or different groups of people (see Epistemic relativism). Not all pluralistic accounts of good reasoning are relativistic, since some accounts entail that different systems of reasoning are equally good for everyone.

Historically, it is probably true that much of the support for normative pluralism among social scientists derived from the discovery (or putative discovery) of descriptive pluralism, along with a certain ideologically inspired reluctance to pass negative judgments on the traditions or practices of other cultures. But normative pluralism was certainly not the only response to descriptive pluralism among social scientists. Many reacted to the alleged discovery of odd reasoning patterns among pre-modern peoples by insisting on monism at the normative level, and concluding that the reasoning of pre-modern folk was ‘primitive,’ ‘pre-logical’ or otherwise normatively substandard. Among philosophers, both historical and contemporary, normative cognitive pluralism is a minority view. The dominant philosophical view is that there is only one good way to go about the business of reasoning, or at most a small cluster of similar ways.

3 Evaluative-concept pluralism

Evaluative-concept pluralism is a descriptive thesis, not a normative one. It maintains that people’s intuitive concepts of cognitive evaluation, concepts like those that we express with terms like ‘justified’ or ‘rational’, vary significantly from culture to culture. If evaluative-concept pluralism is correct, the terms of cognitive evaluation exploited in other cultures or intellectual traditions may differ in both meaning and extension from the terms of cognitive evaluation that are embedded in our own everyday thought and language.

Though the issue is controversial, some philosophers think that evaluative-concept pluralism poses a serious challenge to the tradition of analytic epistemology. That tradition tries to resolve normative questions in epistemology by analysing or explicating our ordinary concepts of epistemic evaluation. If we want to know whether our own system of cognitive processes is better or worse than some alternative system, the analytic epistemologist proposes that we settle the question by determining which system does a better job of producing beliefs that comport with our concept of justification (or rationality) (see Normative epistemology §1). But the analytic epistemologist typically offers us no reason to think that the notions of evaluation prevailing in our own language and culture are any better than the alternative evaluative notions that might or do prevail in other cultures. In the absence of any reason to think that the locally prevailing notions of epistemic evaluation are superior to the alternatives, it is hard to see why we should care whether the cognitive processes we use are sanctioned by those local evaluative concepts.

Imagine that we have located some exotic culture that does in fact exploit cognitive processes very different from our own, and that the notions of epistemic evaluation embedded in their language also differ from ours. Suppose further that the cognitive processes prevailing in that culture accord quite well with their evaluative notions, while the cognitive processes prevailing in our own culture accord quite well with ours. Would any of this be of any help in deciding which cognitive processes we should use? Without some reason to think that one set of evaluative notions was preferable to the other, it seems clear that for most of us it would be of no help at all.

Cohen, Hermann (1842-1918)

Hermann Cohen was the founder of the Marburg School of Neo-Kantianism and a major influence on twentieth-century Jewish thought. Die Religion der Vernunft aus den Quellen des Judentums (Religion of Reason out of the Sources of Judaism) (1919) is widely credited with the renewal of Jewish religious philosophy. Cohen's philosophy of Judaism is inextricably linked with his general philosophical position. But his system of critical idealism in logic, ethics, aesthetics and psychology did not originally include a philosophy of religion. The mainly Protestant Marburg School in fact regarded Cohen's Jewish philosophy as an insufficient solution to the philosophical problem of human existence and to that of determining the role of religion in human culture. Thinkers who favoured a new, more existentialist approach in Jewish thought, however, saw Cohen's introduction of religion into the system as a daring departure from the confines of philosophical idealism.

Cohen identified the central Jewish contribution to human culture as the development of a religion that unites historical particularity with ethical universality. At the core of this religion of reason is the interdependence of the idea of God and that of the human being. Cohen derives this theme from the Jewish canon through a philosophical analysis based on his transcendental idealism.

1 Life and work

Hermann Cohen was the son of a cantor in the provincial town of Coswig in the state of Anhalt. He abandoned his rabbinical studies at the Jewish Theological Seminary (Breslau) after witnessing the rift between reform and orthodox Jews over the divine revelation of the Mishnah (the ancient code of rabbinic law). Seeking orientation in the conflict between religion and modern consciousness, Cohen turned to philosophy and the sciences. After receiving his doctorate at Halle in 1865, he published studies on mythological, philosophical and aesthetic topics (God and the soul, Plato's theory of Forms), influenced by the then compelling idea of a 'mechanism of consciousness'; but he gradually abandoned the methodologies of Helmholtz and Steinthal and immersed himself in the philosophy of Kant. His 1871 exposition of Kant's first critique, *Kants Theorie der Erfahrung (Kant's Theory of Experience)*, brought him to the centre of the Neo-Kantian movement and led to his appointment as a Privatdozent at Marburg. Subsequent publications, especially *Kants Begründung der Ethik nebst ihren Anwendungen auf Recht, Religion und Geschichte (Kant's Justification of Ethics and its Application to Law, Religion and History)* (1877) and *Das Prinzip der Infinitesimalmethode (The Principle of the Method of Infinitesimals)* (1883) made original contributions to Kantian thought. Cohen's mature philosophical system follows the classic structure of Kant's three critiques but projects a fourth part, on psychology, and seeks to establish a 'critical idealism' faithful in broad outline to the tradition of Plato, Descartes, Leibniz and Kant. Cohen ascribed the continuity of this tradition to a perennial philosophical problematic that arises from the idealism inherent in scientific thought.

The Marburg School, represented by Cohen and his colleague Paul Natorp, attracted students from as far away as St Petersburg (Boris Pasternak) and Madrid (Ortega y Gasset). Those who became philosophers - Ernst Cassirer, Nicolai Hartmann, Heinz Heimsoeth and Hans-Georg Gadamer - gradually emancipated themselves from Marburg Neo-Kantianism. But the tendency of some philosophers to ignore Cohen's contributions expressed ideological biases - thus Heidegger's 1929 verdict of having 'overcome' Neo-Kantianism.

In 1876 Cohen succeeded his mentor Friedrich Albert Lange, author of the *Geschichte des Materialismus und Kritik seiner Bedeutung in der Gegenwart (History of Materialism)*, to a highly visible position as practically the only non-baptized Jew to hold a chair in philosophy at a Prussian university. Three years later he found himself compelled to defend Judaism against the charges of Heinrich von Treitschke that it was alien to the values of German culture. From then on, Cohen's public engagement on behalf of Judaism and Judaic studies increased steadily, extending in time to the renewal of Jewish religious philosophy, a field often neglected among the more historically oriented disciplines of *Wissenschaft des Judentums* (the 'Science of Judaism').

From 1903 Cohen was active in the *Hochschule für die Wissenschaft des Judentums* in Berlin, where, after retiring from Marburg, he lectured on the biblical prophets, the Psalms, the Greek philosophical roots of medieval Jewish thought, Maimonides, Descartes, and philosophical psychology (see Maimonides, M.). Shortly before his death, Cohen also helped found an academy dedicated to the science of Judaism, at the suggestion of his former student

Franz Rosenzweig.

2 'Critical idealism' as the basis of the sciences and the humanities

Unprecedented scientific progress in the later nineteenth century speeded the collapse of German Idealism. Empirical studies of brain function eclipsed intellectual inquiries into the nature of thought, and in many philosophy departments experimental psychology displaced traditional philosophy. Opposing the tide of positivism and materialism, Cohen championed idealism both for what he saw as its ethical implications and because he conceived of idealism as the true groundwork of scientific thought. Like his mentor Lange, Cohen did not malign materialism but saw it as a heuristic principle, itself a product of critical thought, a hypothesis meant to make scientific cognition possible. Materialism itself, then, showed the fertility of critical idealism (see Köhnke 1991).

Cohen's logic, set out in *System der Philosophie, Erster Teil: Logik der reinen Erkenntnis (System of Philosophy Part One: The Logic of Pure Cognition)* (1902), constructs transcendental philosophy rather differently from Kant. Beginning not from the senses and the a priori forms of sensibility and thought but from the science found in 'printed books', Cohen finds knowledge grounded in mathematical principles. These are products not of experience but of pure thought. Only such knowledge is relevant for the logic of cognition. The 'being' it discovers is 'given' only in the mathematical abstractions that we metaphorically call laws of nature. Sense perception, then, including the refined perception of the laboratory, must be relegated to the role of a methodological principle. The limited rules of syllogistic logic (based as they are on grammar rather than mathematical ideas) are similarly relegated to the methodology of research. While sense perception and syllogistic logic are tools in the verification of hypotheses, the hypotheses themselves are the 'origin' (*Ursprung*) of the objects of cognition. Hence, the 'logic of the origin' determines the foundation of being in thought: thought as the origin of being. Reflecting the constantly progressing sciences with their shifting paradigms, the system of categories and judgments represented in Cohen's logic is open-ended - quite a contrast to Kant's efforts to find fixed normative patterns in our thinking as earnest of its objectivity.

There are other deviations: most strikingly, Kant's 'thing-in-itself' (noumena) (see Kant, I. §3) is eliminated as a superfluous dogmatic prejudice. In another notable reform, to avoid psychologistic readings of the Kantian a priori that would confuse the a priori forms of consciousness with innate functions of the brain, Cohen identifies the knowing subject as the 'unity of cultural consciousness' (*Einheit des Kulturbewußtseins*). The quest for a unity underlying the distinct 'directions of culture' (science, law, art) was the ultimate goal of Cohen's system. The transcendental conditions of that unity were to be addressed in the final part (on psychology) of Cohen's philosophical edifice, which he did not live to complete.

Cohen's revision of transcendental logic pivots on the 'principle of the infinitesimal method' whose paradigm is the physicist's reliance not on the senses but on mathematical models (1902: 126). Cognition, we find, begins, counterintuitively, in a 'no-thing' and an 'adventurous detour' (1902: 84) in which reason itself constitutes the object: the non-sensory infinitesimal becomes the origin of all finite reality.

The anti-materialist, anti-determinist implications of Cohen's conception of reality come to the fore in the humanities and ethics. Once it is understood that reality is discovered in judgments, not sense experiences, morality seems far less ephemeral than materialism might seem to make it - provided it can be shown that the ethical concept of a human being is the actual operative principle in some valid mode of discourse. Cohen finds such a 'direction of culture' in law, which must presuppose a concept of the human being transcending the biological. Ethics, then, is constructed analogously to logic, with the human being as the analogue of nature and the laws that regulate humanity's historical and political existence as analogues of the laws of nature. Since ethics seeks the principles of a reality that presupposes the idea of a human being, Cohen's *Ethik des reinen Willen (Ethics of Pure Will)* (1904) becomes a philosophy of law.

Ethics, as 'the teaching about the human being', becomes the 'centre of philosophy' and lays the groundwork for all disciplines dealing with the products of human action (law, economics, the humanities). Overawed by the sciences, the humanities have sometimes mistakenly adopted the biological notion of the human being, but what they require is the ethical notion of a human being: ethics is 'the positive logic of the humanities' (1904: 1).

3 Ethics and the philosophy of religion

Will, action and consciousness are the ‘constitutive concepts’ (1904: 389) of an ethics that rests on the ‘methodology of the exact concepts of the science of law’, to which ethics ‘listens attentively for the sake of its problems of person and action’ (1904: vii). Will, action and consciousness are defined in the end so as to unite all ethical concepts. All the actions of a moral subject become transformations of the ‘pure will’. Beyond the bare idea of will, however, the concepts of freedom and autonomy are presuppositions of the realization of any good. For this reason, Cohen introduces into his ethics traditional Jewish concepts of sin and repentance. Religious rather than philosophical, in his view, these concepts introduce a crucial element of morality that ethics alone cannot provide: the concrete individual. The state, the community, and other such social agencies operate in the ideal time of legal progress. But only the individual can originate moral decisions in actual time.

Ethics, strictly conceived, can address the problem of guilt (*dolus*, *culpa*) but not that of sin (*peccatum*). It cannot deal with concrete human failure. For the law has no power over sin in the sense of guilt but only over culpability (1904: 366-). Ethics similarly lacks a principle of self-transformation. But this principle is found in the biblical and rabbinic idea of ‘repentance’ (*teshuvah*). Religion can address the concrete individual; but for ethics, by its very structure, the concrete individual is a mere fiction.

Ethics and religion share the goal of advancing a humane civilization. But ethics deals with individuals only as members of collectivities. Religion is charged with the reconstitution of particular individuals in psychological or liturgical time, redirecting each toward the future, through a regeneration of the individual moral consciousness, whose existence is endangered by transgression of the law.

Ethics orients the philosophy of religion toward interpreting particular truths of faith in so far as they contribute to the ethical goal. Religion must demonstrate that its principles not only do not contradict the progress of the state towards the ethical ideal but contribute to its realization. Such a formal directive cannot by itself generate particular truths of faith. These arise in the self-transformation of mythology into a religion which each faith must achieve, in so far as it has a ‘share in reason’. Religion continuously transforms myths into ethically justifiable truths of faith. Thus a religion of reason can direct the individual and the community toward moral progress by contributing to the generation of moral consciousness. The task of a philosophy of religion is exposition of the truths of faith of a particular tradition, in so far as they can be conceived as transcending its myths (1904: 337, 388, 586).

The correlation of God and man, fully developed only in *Die Religion der Vernunft aus den Quellen des Judentums (Religion of Reason out of the Sources of Judaism)* (1919), serves to clarify both the historical development and the systematic structure of the truths of the Jewish faith: God and man are correlated as coordinates that progressively determine each other. Reason here aims continually to reconstitute the moral direction of the individual and the community by generating the whole set of moral conditions in the language of the Jewish faith. Accordingly, the religious correlation of God and man must construct the whole apparatus of moral responsibility and law within itself as a condition for the regeneration of individual moral consciousness.

Cohen’s thought revolves around this correlational idea of God, which is, for him, the decisive contribution of Judaism to civilization. Even in *Ethik des reinen Willen*, God is the systematic capstone uniting ethics with logic. Addressing the ‘being of the ought’, ethics has no grounding in reality unless the human spirit has recourse to a principle that unites the present reality (nature) with the ideal of its future. The realization of the ethical ideal in the actual world rests on the assumption of a common origin of both nature and man. Cohen (1919) supports the same idea from within the sources of Judaism that are concretized in the speech-acts of the liturgy.

MICHAEL ZANK

List of works

Cohen, H. (1977-) *Werke*, ed. Hermann-Cohen-Archiv am Philosophischen Seminar der Universität Zürich unter der Leitung von Helmut Holzhey, Hildesheim, Zurich and New York: Georg Olms, 18 vols.(Including one published and six forthcoming volumes of minor writings and a forthcoming new edition of *Religion der Vernunft*, the *Werke* constitute the first comprehensive edition of Cohen’s works, with mostly excellent introductions, comparison of editions, notes, and so on.)

Cohen, H. (1871) *Kants Theorie der Erfahrung (Kant’s Theory of Experience)*, ed. G. Edel, Berlin: Dümmler; 3rd

edn, 1918; 1st and 3rd edns repr. in *Werke*, vol. 1.1—1.3, Hildesheim: Georg Olms, 1987.(Volume 1.1 of the *Werke* edition consists of a reprint of the 3rd edition, Berlin, 1918; vol. 1.2 lists the variations between the earlier editions and offers an index; vol. 1.3 is a reprint of the 1st edition. The variations between the volumes indicate the progress from Cohen's first exposition of Kantian thought to his own mature system of philosophy, masterfully analysed by the editor.)

Cohen, H. (1877) *Kants Begründung der Ethik nebst ihren Anwendungen auf Recht, Religion und Geschichte(Kant's Justification of Ethics and its Application to Law, Religion and History)*, Berlin: Dümmler; 2nd edn, 1910.(The 1st edition of this work presented a considerable step beyond a mere exposition of Kantian thought. It is here that Cohen first 'eliminates' the Kantian 'thing-in-itself' and presents the foundation of his own philosophical approach. The 2nd edition is much revised, especially in its programmatic approach to the relation of ethics to the humanities. This edition is to be reprinted in volume 2 of *Werke*.)

Cohen, H. (1883) *Das Prinzip der Infinitesimalmethode und seine Geschichte: Ein Kapitel zur Grundlegung der Erkenntnisskritik (The Principle of the Method of Infinitesimals and its History: A Chapter in the Foundation of the Critique of Cognition)*, Berlin: Dümmler; 4th edn repr. in *Werke*, vol. 5.1, Hildesheim: Georg Olms, with an introduction by P. Schulthess, 1984.(This study first established the link between the method of scientific validity and the principle of the origin of cognition in thought that became the cornerstone of Cohen (1902).)

Cohen, H. (1889) *Kants Begründung der Ästhetik (Kant's Justification of Aesthetics)*, Berlin: Dümmler.(Rounding out the tripartite structure of studies based on Kant's three critiques, this is Cohen's foray into the field of aesthetics. The work found little resonance at the time. It is to be reprinted in volume 11 of *Werke*.)

Cohen, H. (1896) 'Biographisches Vorwort und Einleitung mit kritischem Nachtrag' (Biographical Preface and Introduction with a Critical Postscript), in F.A. Lange (ed.) *Geschichte des Materialismus (History of Materialism)*, Leipzig: Baedecker, 5th edn; repr. in *Werke*, vol. 5.2, with an introduction by H. Holzhey, Hildesheim: Georg Olms, 1984.(F.A. Lange had been Cohen's benefactor in that he was responsible for Cohen's call to the University of Marburg, where Cohen became Lange's successor. Cohen was responsible for several subsequent editions of Lange's best-selling philosophical study of the history of materialism. Yet in his 'Introduction with a Critical Postscript', revised in 1914, Cohen also criticized Lange and gave a précis of his own philosophical programme. The edition of 1896 was hailed by Vaihinger as 'no less than a new foundation of critical idealism'.)

Cohen, H. (1902) *System der Philosophie, Erster Teil: Logik der reinen Erkenntnis (System of Philosophy Part One: The Logic of Pure Cognition)*, Berlin: Bruno Cassirer; repr. in *Werke*, vol. 6, Hildesheim: Georg Olms, 1977.(The first part of the mature philosophical system which is clearly no longer Kantian but original.)

Cohen, H. (1904) *System der Philosophie, Zweiter Teil: Ethik des reinen Willen (System of Philosophy Part Two: Ethics of Pure Will)*, Berlin: Bruno Cassirer, 1904; repr. in *Werke*, vol. 7, with an English introduction by S.S. Schwarzschild, Hildesheim: Georg Olms, 1981.(A philosophy of the relation between state, community and individuals based on the conceptual tools of jurisprudence. Lays the foundations of a moral philosophy of law and of religion.)

Cohen, H. (1912) *System der Philosophie, Dritter Teil: Ästhetik des reinen Gefühls (System of Philosophy Part Three: Aesthetics of Pure Feeling)*, Berlin: Bruno Cassirer; repr. in *Werke*, vols 8 and 9, with an introduction by G. Wolandt, Hildesheim: Georg Olms, 1982.(Cohen's aesthetics aims to unite natural and moral aspects in the sentiments of *Erhabenheit* (sublimeness) and *Humor* (humour). Walter Benjamin was one of the few appreciative readers of this work. Other contemporaries considered it an unreadable book and a collection of professorial ramblings.)

Cohen, H. (1915) *Der Begriff der Religion im System der Philosophie (The Concept of Religion in the System of Philosophy)*, Gießen: Töpelmann; repr. in *Werke*, vol. 10, ed. H. Holzhey, with an introduction by A. Poma, Hildesheim: Georg Olms, 1996.(In this work, dedicated to the Marburg School's discussions on religion, Cohen first argued for an integration of religion into the system of philosophy without 'sublating' it into ethics.)

Cohen, H. (1919) *Die Religion der Vernunft aus den Quellen des Judentums*, Leipzig: Fock; trans. S. Kaplan with an introduction by L. Strauss, *Religion of Reason out of the Sources of Judaism*, New York: Frederick Ungar, 1972.(The title of the first edition included a definite article before the word 'religion' as if to say Judaism was the only religion of reason. Since this seemed contrary to Cohen's opinion, subsequent editions dropped the definitie article, reading *Religion der Vernunft*. Hailed by Julius Guttmann as having renewed the discipline of Jewish philosophy, this work nevertheless failed to have a serious impact until its current rediscovery as a serious interpretation of a classical religion in the spirit of humanistic philosophy.)

Cohen, H. (1924) *Hermann Cohens Jüdische Schriften (Hermann Cohen's Jewish Writings)*, ed. B. Straub, with an introduction by F. Rosenzweig, Berlin: Schwetschke; partial English translation by E. Jospe, *Reason and*

Hope: Selections from the Jewish Writings of Hermann Cohen, New York: W.W. Norton, 1971. (The forthcoming six volumes of *Kleinere Schriften*, published as volumes 13 through 17 of *Werke*, will do away with the unhelpful division between this collection and the one published in 1928. Contains a wealth of material of interest to students of the history of philosophy and religion in Wilhelminian Germany.)

Cohen, H. (1928) *Schriften zur Philosophie und Zeitgeschichte (Philosophical and Political Writings)*, eds A. Görland and E. Cassirer, Berlin: Akademieverlag, 2 vols.(Contains political and philosophical writings that will be reissued in chronological order and integrated with Cohen (1924) in the *Werke* edition.)

Coleridge, Samuel Taylor (1772-1834)

Although much of Coleridge's life and his best critical and creative powers were devoted to the attempt to develop a philosophical system, he is less well known as a philosopher than as a romantic poet. This is partly because many of his writings remained unpublished until recent years; they now shed new light on the extent of his knowledge of intellectual history, and on the significance of his philosophical synthesis.

As a young man, Coleridge was attracted by the materialist philosophies and theories of human nature which had become part of the Enlightenment's 'Science of Man'. These coincided with his support for the drive towards progress and human brotherhood which he thought inspired the French Revolution. At Cambridge (1791-4) religious doubt accompanied his radical politics and he turned from orthodox Christianity to Unitarianism.

Gradually, however, he became dissatisfied with the 'mechanistic' reductive principles of British eighteenth-century thought. His visit to Germany (1798-9) and his subsequent study of German ideas convinced him that here was a spectrum of philosophical insights which was more adequate to the whole *of human nature; one through which 'head and heart' might be reconciled.*

Coleridge's work reflects his experience of a world subject to violent revolutionary upheavals and his sense of widespread intellectual and moral confusion. Becoming convinced in the early years of the nineteenth century of both the intellectual and spiritual value of Christianity, he sought to re-establish a unity between religious faith and experience and critical philosophy. His 'ideal Realism' reconciled elements of Greek and German philosophy with reinterpretations of Judaeo-Christian themes and doctrines, and with the moral lessons he believed history provided. Any sound philosophy must, he insisted, do justice to every *aspect of human nature. He declared that he was not concerned to be 'original' but to provide a new synthesis, and boldly claimed to have been the first to have 'attempted to reduce all knowledges into harmony'; although his copious notes intended for an Opus Maximum, the 'Logosophia', were never organized into publishable form.*

1 Metaphysics

German philosophy showed Coleridge that he was not alone in seeking a new philosophical ground beyond either dogmatic empiricism or ungrounded metaphysical speculation. He was deeply influenced by, for example, Kant, F.H. Jacobi, Fichte and Schelling, but also examined them critically. In general, he believed idealist philosophy had failed to discern the true nature of a 'self' and its inherent relationality. Other central focuses in his work include the dynamic and constitutive nature of Ideas, the primacy of absolute Will over Being or Mind, and the relation of words as 'living powers' to thought and being.

Coleridge's epistemology is inseparable from his moral philosophy. His insistence in the 'Essay on Faith' that conscience is a precondition of true self-consciousness, for example, is related to his theory of Ideas. He is often categorized as belonging to the Platonist and idealist traditions of thought; certainly he rejects the view that Ideas are merely abstract concepts opposed to reality or (as they were for Kant) merely regulative; they are constitutive of the world, and so must never be confused with mere images or objects of thought. He agrees with Plato that ideal and real are not opposed, and with Descartes that all ideas (as opposed to beliefs or opinions) are their own evidence; but his own theory of ideas is coloured by his agreement with Fichte, that if knowledge is possible at all, it begins with an 'act of will'. There has to be an affirmation given to the inner witness of experience and feeling, even in the first step of perception; though at this stage the 'yes' is pure act, not a cognitive response. Like Fichte, he recognized that, without this, philosophy was powerless to refute scepticism; if, on the other hand, ideas have a dynamic of will, then conscience and consciousness must be intimately connected.

Coleridge's theory of ideas is linked to his development of the German distinction between *Vernunft* (Reason) and *Verstand* (Understanding) (see Kant, I. §8; Hegel, G.W.F. §4). Reason is the faculty of Ideas, a unifying, uniquely human faculty which, in its unity with the will, is inaccessible to causal explanation. The Understanding, by contrast, is the faculty of 'speculative intellect'; the power of analysis, of logical deduction, of calculation, quantification and explanation. Reason includes the faculty of imagination, the image of divine creativity. Imagination creates and interprets the symbols through which universal principles or Ideas are revealed in particular form. It recognizes that what appear to the Understanding to be contradictions (for example, a reality

which is both universal and particular) are in fact the necessary polarities by which reality is constituted.

An important theme in Coleridge's writings is that of 'distinction-in-unity'. Drawn from a synthesis of the philosophies of Pythagoras, Plato and the Alexandrian Jew, Philo, with the Christian model of Trinity, this principle provides the basis of his contribution to the debate on the nature of the self and self-consciousness. Distinction-in-unity was not merely a logical, regulative concept but represented dynamic relationship; that through which, for example, the self is constituted. It is also the means of moral development by which individuals become persons. Coleridge argued that the necessary conditions of personhood (relationship, free will, reason and love) require a transcendent source of 'personeity'. His Absolute is a primacy of Will, self-realized in Mind (Idea) and Being. Throughout his mature writings the nature and function of will and 'act' in relation to reason is constantly reassessed.

Coleridge found in Christianity a language through which the principle of self-consciousness was perfectly expressed. The Trinity was representable as 'ipseity' ('this-ness' or 'self-ness'), 'alterity' ('other-ness') and 'community' (the former two realized in relationship). 'Alterity' is symbolized by *Logos* as the 'Word' or Idea of God; God-other-and-the-same, the first principle of relationship. The 'Community' (Spirit) of the Godhead is a self-realizing, self-limiting love of the 'Other' as another Self. These relations, Coleridge argued, constituted the principle of Humanity. The human self is only fully realized in relation to a Thou ('Essay on Faith').

Distinction-in-unity also provided the basis of his philosophy of nature. He agreed with the German *Naturphilosophen* that life must be understood not in terms of organization, mechanisms or configurations of atoms, but as polarities of forces and powers, and their products (see Naturphilosophie). Throughout his life he followed the latest scientific theories and developments in academic journals, and his *Notebooks* reveal strenuous efforts to show how moral and natural philosophy might be reconciled.

Coleridge saw philosophical integrity and linguistic veracity as interdependent. The abuse of language, with its lack of attention to etymology and to the relation of grammar and language to the processes of thought, resulted in intellectual and moral corruption (*Aids To Reflection*, 1825). It was necessary to 'desynonymize'; to understand the unique, living quality of each word, and therefore its true relation to others. Words should reflect their true source - the *Logos*, the incarnate Word of God.

The *Logos*, as the unifying principle of the 'Logosophia', is first an epistemological principle representing the birth of language, of self-consciousness and therefore of philosophy. *Logos* is also an aesthetic medium; as 'Word' it is the archetypal symbol of the revelatory power of words and imagination. As the principle of polarity ('alterity') it is also the 'life and light' of nature's powers, forces and products. Finally, *Logos* may be defined as ideal Humanity (universal and individual).

2 Political philosophy

As a young man, Coleridge was influenced by the political radicalism of friends such as John Thelwall and William Godwin, and by the reforming zeal of Joseph Priestley's Unitarianism (see Priestley, J.). He agreed with the latter's view that Jesus was himself a true radical and a free-thinking teacher whose humanity was devalued by the attribution of divinity. By the mid-1790s he had distanced himself from Godwin's radical atheism and from Thelwall's view of the irrelevance of Christianity to reform. Soon after, he was to become dissatisfied with Priestley's materialism. However, his Bristol Lectures (1795) and his journal *The Watchman* (1796) reflect his continuing admiration for the principles (if not the practical reality) of the French Revolution, his criticism of the established Church, and his critique of property.

Coleridge contributed essays and leaders to newspapers on all aspects of social and political thought: on economics, government, foreign affairs, relations of Church and state, on monarchy, and on representation. He consistently supported the antislavery movement and opposed the bills, acts and political movements that he thought endangered 'nationalty' and the principles of true humanity. As his theory of nationhood developed, based on the relation between 'national church', monarch and state (*On the Constitution of Church and State*, 1830) the tone of Coleridge's political and social criticism changed. His later views are all related to his concept of the state in the widest sense of nation or 'body politic'. This, in its ideal form, contained the unity of state and national church. In any particular historical representation of the idea, national church and state are *opposing* poles. Together with the sovereign, they maintain the harmony and balance of the whole.

Coleridge contrasted ‘party-spirit’ and ‘clanship’ to true ‘national spirit’. On this basis, he denounced the ‘false patriotism’ of the Irish movements for independence and Catholic emancipation. While Roman Catholics were not to be excluded from the Christian church, their fealty to Rome amounted to self-exclusion from the *national* church, and therefore from full citizenship. For this reason, he found that he could not support the 1829 bill for emancipation. Catholics could not, for example, belong to the ‘clerisy’; the leaders who would foster the ideal characteristics of humanity. These would ensure the development of Reason, the religious sense, a philosophical and moral understanding of history, attention to the true meaning of words and a recognition of the state as (potentially) a living unity of Will and Reason rather than a Hobbesian ‘Leviathan’.

‘Nation’, Coleridge agreed with Kant, was not to be identified with ‘people’; he was not a democrat, and did not equate the desires of the aggregate of the people with the interests of the nation. He distrusted the foreshadowings of mass labour movements, as his later notebooks show, declaring them to be the result of bad government which had ignored the moral lessons of history and abandoned the fundamental question of what it is to be human. He vehemently criticized leading politicians and statesmen, such as William Pitt and Charles Grey, for failing to preserve the ‘nationalty’; that is, a reserve for the nation in the form of ‘a *wealth* not consisting of lands, but yet derivative from the land, and rightfully inseparable from the same’. This was the opposite pole to the division of land into ‘propriety’, or ‘hereditable estates’ among individuals; these were ‘the two constituent factors, the opposite, but correspondent and reciprocally supporting, counter-weights, of the *commonwealth*’. He rejected the ‘political economy’ of such thinkers as Adam Smith and Thomas Malthus as ‘a science which begins with *abstractions*, in order to exclude whatever is not subject to a technical calculation’. These ‘abstractions’ it assumes ‘as the whole of human nature’.

Coleridge described the nation as ‘a moral unity, an organic whole’. Its archetype was that of the Jewish people in the time of Moses. Despite his criticism of ‘party-spirit’, he often openly declared the superiority of the English nation; of its constitution, and its development through the creative tension of the opposing principles of ‘progression’ and ‘conservation’. He became increasingly fearful that the nation was under threat of a moral vacuum, but abandoned his earlier political radicalism in favour of philosophical combat against an encroaching ‘mechanism’ that ignored not only the human ideal, but also human nature, need and experience.

List of works

Coleridge, S.T. (1969-) *The Collected Works*, ed. various, Princeton, NJ, and London: Princeton University Press and Routledge.(The grand project of this critical edition, together with the *Letters* and the *Notebooks* will, when complete, represent the whole of Coleridge’s vast achievement, much of it for the first time in published form. Begun at the end of the 1960s, its aim has been to give his writings the widest possible circulation by providing accurate readable transcriptions, and by attempting to make sense of fragments, trace references and allusions by detailed cross-referencing and editorial commentary. The *Collected Works* includes *The Watchman* (vol. 2) and the ‘Essay on Faith’, in the volume *Shorter Works and Fragments*, ed. H. and J.R. de J. Jackson, 1995.)

Coleridge, S.T. (1966-71) *Collected Letters of Samuel Taylor Coleridge*, ed. E.L. Griggs, Oxford: Clarendon Press, 6 vols.(E.L. Grigg’s edition of the *Collected Letters* gives access to Coleridge’s correspondence with family, friends, publishers, fellow scholars, poets and other eminent men and women of his time. They reveal the chronology of his preoccupations, his hopes and fears, the details of his daily life and the development of his thought.)

Coleridge, S.T. (1957-) *The Coleridge Notebooks*, ed. K. Coburn and M. Christensen, Princeton, NJ: Princeton University Press, 5 vols.(*The Coleridge Notebooks* reveal not only the vast range of Coleridge’s reading and his intellectual brilliance and profundity, but show his repeated return to struggle with certain topics and the sources of influence on which he drew. Here are fragments of his thought on the physical sciences, on history, religion, psychology, politics, grammar - all witnessing to his continual attempt to show the ultimate unity of nature and mind, philosophy and religion, thought, feeling and experience.)

Collegium Conimbricense

The Collegium Conimbricense ('Coimbra group') or the Conimbricenses were late sixteenth- and early seventeenth-century Jesuit philosophy professors at the University of Coimbra, specifically in the College of Arts, which in 1555 had been placed under the direction of the Society of Jesus. Encouraged by their religious superiors and especially by Pedro da Fonseca, between 1592 and 1606 the Conimbricenses published five volumes containing eight treatises of commentary on Aristotle. Distributed particularly through the Jesuits, these volumes were widely influential in Europe, America, and the Far East, including Japan and China. On this last, Sommervogel (1891) has cited the seventeenth-century Jesuit, Athanasius Kircher, to the effect that by his time all the Coimbra commentaries had been translated into Chinese.

Chief members of the Collegium Conimbricense were Emmanuel de Goes (1542-97), Cosmas de Magelhães (1551-1624), Balthasar Alvarez (1561-1630), and Sebastian de Couto (1567-1639). In order of appearance, their treatises were: (1) *Commentarii Collegii Conimbricensis Societatis Jesu in octo libros Physicorum Aristotelis Stagyritae (Commentaries…on the Eight Books of Aristotle's Physics)* (1592); (2) *Commentarii Collegii Conimbricensis Societatis Jesu in quatuor libros de Caelo (Commentaries…on the Four Books of On the Heavens)* (1592); (3) *Commentarii Collegii Conimbricensis Societatis Jesu in libros meteorum (Commentaries…on the Books of the Meteorology)* (1592); (4) *Commentarii Collegii Conimbricensis Societatis Jesu in parva naturalia (Commentaries…on the Parva Naturalia)* (1592); (5) *Commentarii Collegii Conimbricensis Societatis Jesu in libros Ethicorum ad Nichomachum (Commentaries…on the Books of the Nicomachean Ethics)* (1595); (6) *Commentarii Collegii Conimbricensis Societatis Jesu in libros de generatione et corruptione Aristotelis Stagiritae (Commentaries…on Aristotle's On Generation and Corruption)* (1595); (7) *Commentarii Collegii Conimbricensis Societatis Jesu in libros de anima Aristotelis Stagiritae (Commentaries…on Aristotle's On the Soul)* (1595) (this work was edited by Magelhães, who added his 'Tractatio aliquot problematum ad quinque sensus spectantium' (A Treatment of Some Problems regarding the Five Senses) and attached a treatise by Alvarez called 'De Anima Separata' (On the Separated Soul), because Aristotle had not discussed the separated soul in the previous books); and (8) *Commentarii Collegii Conimbricensis et Societatis Jesu in Universam Dialecticam Aristotelis (Commentaries…on the Whole Logic of Aristotle)* (1606).

This last volume, which was edited and published by de Couto, shows the Conimbricenses at their best. Through its two main parts, following the style of Fonseca's commentaries on the *Metaphysics* of Aristotle (see Fonseca, P. da §3), they have reviewed individual treatises of the Organon. For each of these, they give the Greek of Aristotle, translate it into Latin, summarize and explain its philosophical doctrine, and then comment on it by raising *questions* which it had occasioned among the scholastics of the sixteenth and earlier centuries. Their scholarship, with regard to Greek, Latin, philosophy and the scholastic tradition before themselves, is quite evident. Evident also is the sincerity and depth of their own philosophical interest.

A good example is the first chapter of their commentary on Aristotle's *De interpretatione*. Entitled *De signo (On the Sign)*, it is more than sixty pages long. While some treatment of signs in Aristotelian commentary was common among the scholastics, these pages of the Conimbricenses represent the first really major seventeenth-century treatise on signs. Five principal issues are raised: (1) the nature and conditions common to signs; (2) the divisions of signs; (3) the signification of spoken words and of writing; (4) whether concepts are the same among all, and (going into the question of a natural primitive language) whether spoken words are different; and (5) whether some concepts in our minds are true or false, and others devoid of truth and falsity. Along the way there are sub-questions about the essence of a sign, the possibility of something being a sign of itself, signs as natural or conventional, signs as formal or instrumental, signs as actual or aptitudinal, the relations involved in signs, and so forth. Although their commentary is a work of logic, the Conimbricenses show awareness of many epistemological, psychological, metaphysical and theological questions which can be raised with regard to signs and signification. They also display a remarkable understanding of the breadth and scope of semiotics itself.

Some of the items which they have touched on in different ways are the following: language, syntactical speech, laughing, nodding, coughing, people talking in their sleep, people lying, people emitting words without thought. They consider the signification of negative words, of syncategorematic words such as 'if', nonsense words like

'Blictri', and words like 'chimera' and 'goat-stag' to which no real things correspond. They are interested in the signs involved in writing and reading, especially voiceless reading. Coupled with a short discussion of the physiological bases of speech and hearing, they treat the relation between deafness and an inability to speak or communicate. Relying on Herodotus' account of King Psamittachus, who deliberately reared children with animals to see what language they would naturally speak, as well as on an account, from Jesuit missionaries at the court of Akbar the Great, Mogul of India, of a similar experiment conducted by that prince in 1596, the Conimbricenses discuss the language of what amount to feral children. Probably also relying on accounts of Portuguese Jesuit missionaries, they briefly speak of the difference between written languages which use pictograms (they mention hieroglyphics, as well as Chinese and Japanese characters) and those which use an alphabet. Connected with this they touch upon the signification of arithmetical numbers as well as astronomical signs. Topics occasioned by the Bible are the language of Adam and Eve, the language of Adam when giving 'proper' names to the animals, the sign of Cain (which following St Jerome they regard as a tremor), the rainbow given to Noah, and the phenomenon of different languages at the Tower of Babel (see Language, Renaissance philosophy of §2). In the area of zoosemiosis, they mention Aristotle's study of the song of birds, and they discuss the formation of words by parrots and magpies, as well as different kinds of communication among brute animals. Against a general background of optics, they discuss images as signs, especially images in mirrors. While it does not fully express their semiotic theory, one very revealing sentence is the following: 'There is nothing which leads to the cognition of anything else which cannot be reduced to some sort of sign' (*In universam dialecticam* II q.2 a.3).

Collier, Arthur (1680-1732)

Arthur Collier was an English parish priest who arrived, independently, at a version of immaterialism strikingly similar to that of Berkeley. In his 1713 work Clavis Universalis ('universal key'), Collier contends that matter exists 'in, or in dependence on' the mind. Like Berkeley, he defends immaterialism as the only alternative to scepticism. He admits that bodies appear to be external, but their apparent or 'quasi' externeity is, he argues, merely the effect of God's will, and not a sign of 'real' externeity or mind-independence. In Part I of the Clavis, Collier argues (as Berkeley had in his New Theory of Vision) that the visible world is not external. In Part II he argues (as Berkeley had in both the Principles and the Three Dialogues) that the external world 'is a being utterly impossible'.

1 Life

Collier was born at Langford Magna, near Salisbury in Wiltshire, England. He entered Pembroke College, Oxford in 1697 and transferred to Balliol in 1698. In 1704 he became rector of Langford Magna, a position he held until his death. While at Langford, Collier may have met John Norris whose *Essay towards a Theory of the Ideal or Intelligible World* (1701/4) he admired. Norris argued that the existence of the external world could not be demonstrated, but he did not deny that it exists. In the *Clavis Universalis* (1713) Collier set out to demonstrate this more radical conclusion.

By 'external', Collier writes, 'I understand the same as is usually understood by the words, absolute, self-existent, independent, etc.' ([1713a] 1909: 6). 'All matter, body, extension, etc. exists in, or in dependence on mind, thought, or perception, and…is not capable of an existence, which is not thus dependent' - dependent, that is, not on any mind in particular, but on 'some mind or other'. There is, in fact, a material world in the mind of God that is numerically distinct from the world perceived by any of God's creatures. Collier insists that he makes 'no doubt or question' of the existence of bodies. But their existence, he contends, is an 'in-existence'. He compares it to the existence of objects seen in a mirror, and to the images that float before a fevered imagination.

2 The visible world

The *Clavis* is divided into two main parts: in the first, Collier, 'content for a while to grant that there is an external world' ([1713a] 1909: 33), argues that the visible world is not external; in the second, he argues that an external world is utterly impossible. The first part begins with the argument that we cannot justly infer real externeity from visible or apparent externeity. Sounds, smells, tastes and heat, which seem to exist 'altogether without' the mind, have been proven by Descartes, Malebranche and Norris to exist entirely within it. Light and colours, objects of sight which seem to be distant from or external to the mind, are not really external at all, any more than the visions seen by prophets, or the delusions of drunkards and madmen. If Apelles imagines a centaur, Collier says, the centaur seems to be external, even though it is, as an object of imagination, wholly within the mind. God can turn the imaginary object into an object of sight, he proposes, without creating an external centaur, simply by *intensifying* Apelles' perception. The faint and languid image of a centaur will then become a vivid perception or object of sense. All the difference between imagining and seeing, Collier contends, is a difference of degree.

Collier offers several reasons why visible objects are not and cannot be external. If we press our eye as we look at the moon, we see two moons, not one. Both moons are equally vivid and they seem to be equally external. It follows, he claims, that either both are external or neither is. But 'we are agreed…that they are not both so' ([1713a] 1909: 30). He therefore concludes that neither moon is external, observing that this pattern of reasoning can be extended to any visible object whatsoever. A second argument purports to show that the moon in the heavens is not the moon that humans see. The moon in the heavens is dark, opaque, spherical and large; the moon that humans see is luminous, flat and 'so little, as to be entirely covered by a shilling' ([1713a] 1909: 33). According to a third argument, a thing can be seen only if it is present to our mind. But an object cannot be present to the mind if it is external to it. Hence a visible object cannot possibly be external.

Part 1 of the *Clavis* concludes with a series of objections and replies. According to one objection, Descartes has shown that the existence of an external world can be derived from the goodness of God. Collier replies that although we are inclined to believe in an external world, the judgment that there is such a world is not involuntary.

If it is mistaken, the blame falls not on God but on ourselves.

3 The external world

Part 2 of the *Clavis* is as relentlessly argumentative as Part 1: Collier presents nine separate arguments against an external world and concludes by replying to three objections. He begins by arguing that because an external world must be invisible (as established in Part 1), it must be unknowable. This is, he admits, no 'demonstration' that there is no external world, but it is 'near of kin to demonstration' and serves the same purpose, because it is an acknowledged rule of reasoning that an unknown thing should never be supposed to exist. Later he considers the objection (attributed to Malebranche) that Scripture assures us of an external world. Collier replies that it does not. He expands on his reply in *A Specimen of True Philosophy* (1730), where he develops an immaterialist interpretation of the opening verse of Genesis.

Collier's second argument is that God would have no reason to create an external world. It is therefore 'extrinsically impossible', or impossible in view of its cause. He goes on to claim, in arguments that resemble Kant's first and second antinomies, that it is also 'intrinsically impossible', or impossible in its own nature (see Kant, I. §8). He argues, for example, that the external world is both finite and infinite. The contradiction can be avoided, he claims, only by denying that the world is external to the mind. Arthur O. Lovejoy and Ethel Bowman are among the commentators who have noticed the resemblance to Kant. As Lovejoy (1908) points out, a German translation of the *Clavis* (bound with a translation of Berkeley's *Dialogues*) was published in 1756, but as Lovejoy admits (and as H.J. de Vleeschauwer (1938) argues in more detail) there is no persuasive evidence that Kant was actually influenced by Collier.

Collier also argues that because the external world is a created thing, it must 'subsist on the mind, or will, or power, of God' ([1713a] 1909: 87). He also argues, much as Berkeley had, that philosophical definitions of matter come to nothing, and that if the world is external, there is no theory of vision compatible with our seeing it. In a brief conclusion, Collier surveys the consequences of his doctrine. The survey is meant to fulfil his promise of a 'universal key' - a way of unlocking 'almost all the general questions that [the reader] has been used to account very difficult, or perhaps indissoluble' ([1713a] 1909: 131) - but apart from observing that his doctrine undermines the Catholic doctrine of transubstantiation, Collier discusses no particular question in detail. He admits that ordinary language is almost wholly built on the supposition of an external world. But he is no more disturbed by this than he was by the objection that the external existence of the visible world enjoys universal consent. Indeed the motto on the title page of the *Clavis*, borrowed from the Latin translation of Malebranche's *Search after Truth*, boldly proclaims that 'the popular approval of an opinion on a difficult matter is a certain sign of falsehood'.

4 Collier and Berkeley

Some scholars suspect that Collier deliberately concealed his debt to Berkeley; most accept his report (in the first paragraph of the *Clavis*) that he arrived at his views ten years before he published them. Collier first refers to Berkeley in letters written in 1714-15. In *A Specimen of True Philosophy* (1730), he writes that 'except a single passage or two' in Berkeley's *Dialogues*, there is no other book 'which I ever heard of in the World' on the same subject as the *Clavis* (1730: 21). This is a puzzling remark on several counts, one being that in the Preface to the *Dialogues*, Berkeley describes both of his earlier books. Robert Benson, Collier's biographer, reports seeing among his papers an outline, dated 1708, on the question of the visible world being without us or not, but says no more about it. Benson concludes that Collier's independence cannot reasonably be doubted; perhaps the outline would, if unearthed, establish this. There is, however, internal evidence for Collier's independence. As Charles J. McCracken (1983) shows, Collier's most important arguments have parallels in Malebranche and John Norris (who are among Collier's acknowledged sources) and in Bayle (who is not). If we are determined to find Collier unoriginal, then we can do so without supposing that he borrowed from Berkeley.

List of Works

Collier, A. (1713a) *Clavis universalis: or, a new inquiry after truth. Being a demonstration of the non-existence, or impossibility, of an external world*, London: printed for R. Gosling; ed. E. Bowman, Chicago, IL: Open

Court, 1909; repr. New York: Garland, 1978.(Collier's defence of immaterialism. The Bowman edition has an introduction and notes.).

Collier, A. (1713b) *Christian principles of obedience to the higher powers. In a sermon preach'd…at the cathedral church of Sarum* [Salisbury], London: Printed for R. Gosling.(On the subjection of Christians to civil authority.)

Collier, A. (1716) *Of justification by faith, as in opposition to justification by works: in a sermon… preached at the cathedral church of Sarum* [Salisbury], London: Printed and sold by J. Downing.(Concludes with some remarks on systems of ethics.)

Collier, A. (1730) *A specimen of true philosophy in a discourse on Genesis: the first chapter and the first verse*, Sarum [Salisbury]: Printed by Charles Hooton.(An immaterialist interpretation of the opening verse of *Genesis*.)

Parr, S. (ed.) (1837) *Metaphysical tracts by English philosophers of the eighteenth century*, London: E. Lumley; repr. Hildersheim: Georg Olms, 1974; repr. Bristol: Thoemmes Press, 1992.(Includes both the *Clavis* and *A Specimen of True Philosophy*.)

References and further reading

Benson, R. (1837) *Memoirs of the life and writings of the Rev. Arthur Collier*, London: E. Lumley; repr. Bristol: Thoemmes Press, 1990.(A biography, with long selections from Collier's correspondence. Chapter 2 contains several letters of philosophical interest. Collier's theological views, examined in Chapter 3, are summarized in an unpublished manuscript that appears as Appendix A.)

Eschenbach, J.C. (1756) *Sammlung der vornehmsten Schriftsteller die die Würklichkeit ihres Eignen Körpers und der ganzen Körperwelt Läugnen (A collection of the leading authors who deny the reality of their own bodies and of the whole corporeal world)*, Rostock: A.F. Röse.(Contains German translations of both the *Clavis* and Berkeley's *Dialogues*, with extensive critical notes.)

Johnston, G.A. (1923) *The Development of Berkeley's Philosophy*, London: Macmillan.(For Berkeley's relation to Collier see Appendix I, pages 360-82. Refers to earlier discussions of Collier by Thomas Reid and Dugald Stewart.)

Lovejoy, A.O. (1908) 'Kant and the English Platonists', in *Essays Philosophical and Psychological in Honor of William James*, New York: Longman, Green, 1908, 265-302.(Kant and Collier are discussed on pages 284-90.)

McCracken, C. (1983) *Malebranche and British Philosophy*, Oxford: Clarendon. (Chapter 5 includes an accessible survey of Collier's main arguments, emphasizing his debt to Malebranche and Norris.)

Vleeschauwer, H.J. de (1938) 'Les antinomies Kantiennes et la *Clavis Universalis* d'Arthur Collier' ('The Kantian antinomies and the *Clavis Universalis* of Arthur Collier'), *Mind* 47: 303-20.(Argues against the suggestion that Collier influenced Kant.)

Collingwood, Robin George (1889-1943)

Collingwood was the greatest British philosopher of history of the twentieth century. His experience as a practising historian of Roman Britain led him to believe that the besetting vice of philosophy is to abstract propositions away from the context of the practical problems and questions that gave rise to them. Until we know the practical context of problems and questions to which a proposition is supposed to be an answer, we do not know what it means. In this respect his concern with the living activities of language users parallels that of the later Wittgenstein. Collingwood also believed that the interpretation of others was not a scientific exercise of fitting their behaviour into a network of generalizations, but a matter of rethinking their thoughts for oneself. His conviction that this ability, which he identified with historical thinking, was the neglected and crucial component of all human thought stamped him as original, or even a maverick, during his own lifetime. He also shared with Wittgenstein the belief that quite apart from containing propositions that can be evaluated as true or false, systems of thought depend upon 'absolute presuppositions', or a framework or scaffolding of ideas that may change with time. The business of metaphysics is to reconstruct the framework that operated at particular periods of history. Collingwood had extensive moral and political interests, and his writings on art, religion and science confirm his stature as one of the greatest polymaths of twentieth-century British philosophy.

1 Overview

Collingwood was born in the Lake District of England, and educated until the age of 13 by his father, a painter and friend of Ruskin. It was during his childhood that he absorbed his admiration for practical problem-solving, whether the problems were those of a painter, an archaeologist or a sailor: 'I learned to think of a picture not as a finished product exposed for the admiration of virtuosi, but as the visible record…of an attempt to solve a definite problem in painting, so far as the attempt has gone' (1939: 2). He subsequently attended Rugby School and University College, Oxford, where he had a brilliant career as a classicist. He was the only pupil of F.J. Haverfield, the Romano-British historian, to survive the First World War, and conceived it his duty to carry on Haverfield's work. So he effectively combined two careers, as a teacher of philosophy at Pembroke College, Oxford, from 1912, and as a practising archaeologist and classicist. In the second capacity he made extensive contributions to the corpus of Roman inscriptions recorded in Britain, and wrote the sections on Roman Britain in the *Oxford History of England*. Although in his *Autobiography* (completed in 1938) he liked to portray himself as a philosophical outsider, his distinction was acknowledged by the Waynflete Chair of metaphysical philosophy, to which he was elected in 1936, and which he held until a series of strokes forced him to retire in 1941.

Collingwood characterized the philosophical situation at the Oxford of his time as one of opposition between the lingering 'school of Green' and the 'realists', whose members included John Cook-Wilson, H.W.B. Joseph and H.A. Prichard. Similar tendencies to realism in Cambridge were represented by G.E. Moore and Bertrand Russell. By the 'school of Green' Collingwood referred to what is often called 'absolute idealism', although he is careful to note that the leading representative of that school in his time, F.H. Bradley, repudiated the label of idealist, as Collingwood himself did. Although educated as a realist, Collingwood locates his progressive disenchantment, in the years before the First World War, in his realization that the historical understanding that the realists brought to philosophy was totally inadequate. Moore criticized Berkeley for views which Berkeley never held; Cook-Wilson criticized Bradley for views that Bradley never held. As a historian Collingwood found himself offended by the lack of historical scholarship demonstrated by such performances. He differs from the analytic tradition most fundamentally over history. If one reads Moore, or Wittgenstein, it might seem that philosophy and history have nothing to do with one another, and if Moore made a historical mistake about Berkeley, that need not diminish the importance of his philosophical thought. But Collingwood sees thought as something that is essentially historically embodied: the idea of a worthwhile philosophy with no reflection on its own historical situation would be a contradiction. We can understand where we are only by understanding our own historical embedding: how we got there and the thoughts of those who would wish us to have got somewhere else. For Collingwood, therefore, there is no split, of the kind that has been made much of in recent philosophy, between treating historical philosophers as great, but unlearned, contemporaries and treating them as historical material: in all the important respects, the past lives in the present and the present cannot be understood without it (see History, philosophy of §4).

2 Major themes

According to Collingwood, the realists of his time thought of knowledge as the static, direct apprehension of the truth of a proposition: a mysterious unity that arises when mind confronts fact. Collingwood, making use of his experience as a working historian, insisted that knowledge is never that, but must be the outcome of a moving, active, dynamic process of hypothesis formation and testing. Questioning is one half of the act of which the other half is forming an answer, and it takes both halves to make up a situation of knowing anything. It should be noticed that this is not an opposition to realism on behalf of any kind of idealism, and the label is of little diagnostic value in attempting to understand Collingwood.

Applying this doctrine to the interpretation of historical texts, Collingwood insists that you cannot know what a philosopher meant by a doctrine until you know the question to which the doctrine was intended as an answer and how that question arose. Immediately it follows that you cannot tell whether propositions contradict each other unless you know that they are answers to the same question. This is partly a plea for intelligent appreciation of the space of problems within which different writers work, and in effect Collingwood is highlighting a version of what later became called the principle of charity (see Charity, principle of §1). Indeed, he sometimes embraces one extreme consequence of a method based on the principle of charity, namely that since we have to read the questions to which philosophers address themselves back from their answers, there is no possibility of saying that their answers are inadequate or muddled or mistaken. Using his favourite analogy of naval history he asks: 'How can we discover what the tactical problem was that Nelson set himself at Trafalgar? Only by studying the tactics he pursued in the battle. We argue back from the solution to the problem' (1939: 70). He himself notes that this works at least mainly because Nelson won the battle, and we may legitimately wonder whether it is right to assume that the great dead philosophers won all their battles. But for Collingwood the integrity of the historical quest requires interpreting them substantially as if they did.

The upshot is that the scope for fundamental criticism of a philosopher diminishes markedly, and this leads to the second theme of constant importance to Collingwood: the identification of metaphysics with history. At first blush it may seem that he must believe that metaphysics, at least as it is done in critical discussion of the views of great past thinkers, has been entirely superseded by the historical problem of discovering the questions and answers they are proposing. However, the twist is that solving this historical problem, for Collingwood, requires reliving the problem and rethinking the issue for oneself. It requires making the words of the text into one's own, re-centring one's concerns and seeing how these things are to be said or these actions performed in answer to them. So if the metaphysical problem gives way to a historical one, it is equally true that a historical problem gives way to a metaphysical one: for example, to understand Plato historically requires fully grasping the problem to which the theory of Forms provides an answer.

Collingwood's *rapprochement* between history and metaphysics here depends upon his insistence that historical thinking is in this way a matter of living through the thinking of the person confronted with a problem. This is perhaps the best-known of his doctrines, and he has several interlocking reasons for it. He holds that to study a person in respect of their mental features is to study their own self-understanding, and that means the concepts that determine their plans and activities. Understanding these concepts is not an atomistic project, a matter of finding individual elements, perhaps written in the brain, connected by scientific law with other elements. It is an essentially holistic enterprise that needs to draw on the wider knowledge of the person's human context. When I come to understand why you acted as you did I am not concerned to place you in a law-like causal network, but to see the point of your doings. In the modern jargon, rationalizing you is a distinct normative activity, not reducible to seeing your behaviour just as part of what generally happens, part of a scientifically repeatable pattern. By the normativity of thought Collingwood means not just that as bystanders we can assess the thoughts of others for truth or falsity, rationality or the reverse. He means that thinking itself is essentially a process of which such assessments are a part. The thinker is actively engaged in solving a problem, and is constantly evaluating proposals, withdrawing some and improving others. What is being done cannot be clocked or recorded or understood in terms of a succession of passive occurrences.

In all his works, from the early *Religion and Philosophy* (1916), he opposes this theory of interpretation to 'scientific' psychology. He sees the scientific psychologist as one who treats the phenomena of mental life as natural events, surveyable from the outside, and who seeks to generate laws of association and development. But, he says, the mind regarded in this way ceases to be a mind at all. He has no objection to this treatment of essentially passive mental phenomena, such as he takes feelings to be. It is when the approach is tried upon

thinking that he objects. He is at his most scathing when describing the grotesque failure of psychologists of his day to engage with thought, even when they purport to be giving its scientific nature. His critique goes to the heart of the question of method in gaining human understanding. For although he calls his epistemology a theory of history, it is what is with less dignity called a theory of folk psychology (see Folk psychology). He is quite clear that he is not only concerned with the remote past: ‘If it is by historical thinking that we re-think and so rediscover the thought of Hammurabi or Solon, it is in the same way that we discover the thought of a friend who writes us a letter, or a stranger who crosses the street’ (1946: 219) - and, he adds, our own thoughts of ten years or five minutes ago. The inclusion of self-knowledge is deliberate and impressive, for Collingwood held that there was no division between knowing one’s own mind and knowing that of others. In this respect his approach is more sophisticated than the *verstehen* method of Wilhelm Dilthey. Its closest successor in current philosophy is the view that ascription of belief and desire to others is best seen as an ‘off-line simulation’ of their active processes of thought. Collingwood’s view that the self-controlling normativity of thought unfits it for being the subject of a self-standing science strikingly anticipates the later discussions of interpretation of others given by writers such as Davidson and Dennett. His hostility to the external, objectifying, professedly ‘scientific’ approach to the human world is as radical as anything to be found in more recent debates.

A final theme that can be isolated as a constant in his work is the dependence of all thought upon absolute presuppositions. Collingwood is not here thinking of the a priori, for, this time anticipating Quine, he has no use for the category. Rather, at a particular time the identification of questions and the production of answers in response to them must go on against a largely unnoticed background of presuppositions. These themselves are not posed in answer to any questions, and therefore cannot be assessed as true or false. To use the analogy with which Wittgenstein in *On Certainty* characterized the same doctrine (which he held for the same reason - the absence of a method for raising and answering the question of truth) they are the hinges on which the door swings. Collingwood has in mind something like the paradigms of Thomas Kuhn: the resources for thought and the devices for structuring it that, in a particular period of time, form the framework within which ordinary investigation proceeds. Again, his prescience in isolating such a category and insisting that historical research be directed at uncovering its operations in the history of science and philosophy has been amply confirmed by later writing.

3 Other works and topics

If one thinks of British philosophy of the 1920s and 1930s as mainly concerned with Russellian and Moorean approaches to mind and matter, or as easing itself into some kind of relationship to logical positivism, then Collingwood’s interests will seem unusual. His first attempt at a system of his own is *Speculum Mentis* (1924), which reviews five forms of experience as modes of discovering the truth. These are art, religion, science, history and philosophy. Art and religion stand at the bottom, since neither aims at expressed knowledge, although religion aims at symbolizing our relationship with the world. Science aims at truth, but its categories are inadequate to capture human experience. History suffers because historians can be seen as spectators of the events that they write down, and their own perspectives are distorting influences. Only in philosophy does the possibility of transcending these partial perspectives arise, and with it an understanding of the relative place of the four inferior modes of experience. The hierarchy of different modes of knowledge is an example of what he later explored as a ‘scale of forms’ or dialectically related set of categories whereby the essence of a phenomenon becomes more perfectly instanced. There are echoes here of the idealism to which Collingwood was not formally committed. His later reaction to this work was that it misunderstood the nature of history: historians are not spectators, but by reliving past thought become one with the histories they are writing (see Oakeshott, M. §2).

The theme of artistic experience is the topic of his justly famous *The Principles of Art* (1938). Collingwood considers, and rejects, several views about the nature of art: that it is craft, representation or imitation, magic or amusement. He finds its essence in expression and imagination, which gives definite form to what is hitherto unconscious. Arguably the least successful part of the work is the attempt to examine what is involved in expression, which leads to the paradoxical doctrine that successful artists achieve their success in their own imagination, while externalizing or expressing what has been imagined is mere craft. This separation of thought and expression seems to witness a surprising and naive separation of mind and body, and his full view may be more complex. He certainly held, for instance, that there is no such thing as an unexpressed emotion (1938: 238), which is hardly consistent with a simple-minded dualism.

Throughout his life Collingwood wanted to put his theoretical concerns into close relationship with practical, moral and political activity. His deep hostility to utilitarianism, especially visible in his *Essays in Political Philosophy* (1989) and *The New Leviathan* (1942), probably originated in the work of the 'school of Green' although it is also fertilized by continental moral philosophy. Proper living, for Collingwood, is not the repeated satisfaction of a stream of arbitrary desires or caprices, but an exercise of rational, free agency, in conformity with duty. Rationality and freedom are equated with knowledge. Collingwood here sympathized not only with Kant, but with the tradition of European liberalism of such writers as Giovanni Gentile and Guido de Ruggiero. For such thinkers the conditions for freedom include an especial sort of community, whose members acknowledge the same freedom in each other, and in which the institutions are organized so as to promote this mutual recognition (see Freedom and liberty §2). Like Benedetto Croce, Collingwood believed that, properly understood, liberalism tempers democracy with aristocracy. In any body politic there will be rulers and ruled; the rulers will be objects of emulation, and therefore under an obligation to comport themselves aristocratically, in the sense of possessing full awareness of the dignity due to their station. In a liberal society the ranks of the rulers would be replenished from those of the ruled, and systems of education and freedom of ideas would be the devices for ensuring the ongoing quality of the intake.

Collingwood's writing is undoubtedly infuriating. Along with passages and doctrines of great depth and interest there are casual formulations of argument and a rather donnish delight in pugnacious overstatement and paradox that have left him easy prey to unsympathetic critics. Nevertheless the depth and range of his thought have seldom been equalled, and the years since his death have only slowly revealed the central importance of his problems, and the interest of his discussions of them.

SIMON BLACKBURN

List of works

Collingwood, R.G. (1916) *Religion and Philosophy*, London: Macmillan.(A juvenile work notable for its containing the equation of history and philosophy.)

Collingwood, R.G. (1924) *Speculum Mentis*, Oxford: Oxford University Press.(The first attempt at a systematic metaphysics, relating different areas of knowledge: art, religion, science, history and philosophy.)

Collingwood, R.G. (1933) *An Essay on Philosophical Method*, Oxford: Oxford University Press. (An attempt to interpret philosophy through the different 'forms' of the categories that it treats; the work is vaguely reminiscent of Kant.)

Collingwood, R.G. (1938) *The Principles of Art*, Oxford: Oxford University Press.(The most influential and readable work on aesthetics in English.)

Collingwood, R.G. (1939) *An Autobiography*, Oxford: Oxford University Press.(A slightly paranoid but amusing exercise in self-interpretation.)

Collingwood, R.G. (1940) *An Essay on Metaphysics*, Oxford: Oxford University Press.(A rejection of positivism in favour of metaphysics as the science of the presuppositions of thought at a time.)

Collingwood, R.G. (1942) *The New Leviathan*, Oxford: Oxford University Press.(Collingwood's only treatise on political philosophy, celebrated for its equation of freedom and knowledge.)

(1945) *The Idea of Nature*, Oxford: Oxford University Press.(A superb and under-appreciated exercise in the history and philosophy of science.)

(1946) *The Idea of History*, Oxford: Oxford University Press.(Collingwood's most widely read and influential work, covering history and historiography from Herodotus to Toynbee and Spengler.)

(1989) *Essays in Political Philosophy*, ed. D. Boucher, Oxford: Clarendon Press.(Diverse essays from 1924 onwards, concerned both with the structure of political association and the underpinnings of civilization.)

Boucher, D. (1989) *The Social and Political Thought of R.G. Collingwood*, New York: Cambridge University Press.(A clear and useful guide to Collingwood's political thought.)

Donagan, A. (1962) *The Later Philosophy of R.G. Collingwood*, Oxford: Clarendon Press.(A predominantly hostile presentation of Collingwood from the standpoint of the following generation of Oxford philosophy.)

Dussen, W.J. van der (1981) *History as a Science: The Philosophy of R.G. Collingwood*, The Hague: Nijhoff.(A scholarly and close reading of the major writings on history, including commentary on his work as a historian.)

Mink, L.O. (1969) *Mind, History, and Dialectic*, Bloomington, IN: Indiana University Press.(Probably the best overall introduction to Collingwood. It includes revealing discussions of the 'scale of forms' and

Collingwood's more general metaphysical standpoint.)

Collins, Anthony (1676-1729)

Anthony Collins was an English freethinker, best-known to philosophers for his reconciliation of liberty and necessity, and his criticisms of Samuel Clarke's arguments for the immateriality and immortality of the soul. 'I was early convinced', Collins wrote, 'that it was my duty to enquire into, and judge for my self about matters of Religion' (1727: 4). This is a fair summary of Collins' lifelong project: to judge the claims of religion as an impartial scientist would judge the claims of a theory, not by 'the Way of Authority*', but by reason or 'the* Way of private Judgment*' (1727: 107). Collins took on almost the whole of religion as affirmed and practised in the eighteenth-century Church of England: its philosophical foundations, its theological doctrines, its methods of scriptural interpretation and its views on the politics of church and state. He found most of it wanting. His conclusions were at least deistic and perhaps atheistic (though he remained a practising member of the established church): the irony of his writing and the reactive character of virtually everything he published make it difficult to know for sure.*

1 Life

Collins was born in Middlesex, England. He studied at Eton and at King's College, Cambridge (though he did not stand for a degree), and later studied law at London's Middle Temple. When he married his first wife in 1698, his father gave him an estate in Essex. There Collins met John Locke, who was living in retirement nearby, and in the last two years of Locke's life they became devoted friends. Locke's rationalism was an important early influence on Collins. A second important personal influence was the French refugee intellectual Pierre Desmaizeaux. Collins also knew John Toland, who visited Collins several times at his country home. Collins travelled to Holland in 1711 and 1713, where he met Jean Le Clerc. Between 1717 and 1724 he played an active role in Essex government, serving, for example as county treasurer.

2 The defence of freethinking

In his first book, *An Essay concerning the Use of Reason, in Propositions whereof the Evidence is Human Testimony* which appeared anonymously in 1707, Collins had worked to establish the authority of reason over matters of religion. He had, for example, rejected the prevailing distinction between what is *agreeable to* reason, what is *contrary to* reason and what is *above* reason, insisting that every belief belongs in one of the first two categories. If a report of a miracle is consistent in itself and is compatible with what we know intuitively or demonstratively, then it is, so far, not contrary to reason. It is agreeable to reason if the witness reporting it is credible, and contrary to reason if not.

Collins' full-scale defence of the authority of reason came in his anonymously published *A discourse of free-thinking* (1713). He defines freethinking as 'the Use of the Understanding, in endeavouring to find out the Meaning of any Proposition whatsoever, in considering the nature of the Evidence for or against it, and in judging of it according to the seeming Force or Weakness of the Evidence' (1713: 45). Everything Collins published in his lifetime performs one or more of the three tasks identified in this definition: determining meaning, assessing evidence and judging in accordance with the evidence. According to Collins' theory of judgment (as presented in his 1717 work *A Philosophical Inquiry concerning Human Liberty*), we cannot help but judge according to the 'apparent degrees of light' - the apparent evidence - that propositions possess. His plea for freedom in judgment, then, is really a plea that our pronouncements not be forced to diverge from what the evidence indicates.

Collins' main argument for freethinking is that truth is good (required by God, useful to society, neither forbidden by God nor hurtful to anyone), and that there is no way to discover it except by applying reason. Against this there was one particularly pressing objection: true opinion (not *reasoned* true opinion) is what salvation depends on, and true opinion can be arrived at by revelation. Reasoning would either reinforce revealed truth (in which case it would be superfluous) or subvert it (in which case it would deprive us of the most vitally important thing). It seems that reasoning is hardly worth the risk. Collins' response to this objection is largely implicit. He distinguishes between 'what God speaks plainly to the whole World' - what God says to the reasoning power with which everyone is endowed - and 'what [some] suppose he has communicated to a few' (1713: 72). He then argues that claims to revelation can be evaluated only by reason. (He takes evident pleasure in documenting priestly disagreements about the interpretation of Scripture - disagreements that reason alone can adjudicate.) What God

speaks plainly to everyone, he insists, is that 'he can require nothing of Men in any Country or Condition of Life, but that whereof he has given them an opportunity of being convinc'd by Evidence and Reason in the Place where they are, and in that Condition of Life to which Birth or any other Chance has directed them' (1713: 30). The good of society is, he argues, 'the *Rule* of whatever is to be allow'd or restrain'd' (1713: 90), and it is a mistake to think that removing restraints on reason would breed disorder.

Richard Bentley's *Remarks upon a Late Discourse of Free-Thinking* (1713) is best-known for its criticisms of Collins' classical and Biblical scholarship, but Bentley also objects to Collins' conception and defence of freethinking. Bentley thinks his definition is trivial, 'for it comprehends the whole herd of Human Race, even Fools, Madmen, and Children; for they use what *Understanding* they have; and judge as things *seem*' (Bentley 1713: 10). Collins' definition is really a definition of the understanding; it contains 'not a Syllable about *Freedom*' (Bentley 1713: 10), and in practice, Collins' so-called freedom is nothing but 'an inward Promptness and Forwardness to decide about Matters beyond the reach of [the freethinkers'] Studies, in *opposition* to the rest of Mankind' (Bentley 1713: 11). Collins' oppositional creed, in Bentley's opinion, amounts to atheism:

> that the Soul is material and mortal, Christianity an imposture, the Scriptures a forgery, the Worship of God superstition, Hell a fable, and Heaven a dream, our life without providence, and our Death without hope like that of Asses and Dogs.
>
> (Bentley 1713: 14)

There is, according to Bentley, an 'occult meaning' in Collins' discussions of disputes about scripture: 'from the variety of Scripture to insinuate none is true' (Bentley 1713: 45), (see Bentley, R.).

3 Liberty and necessity

In his first book Collins briefly defended a version of compatibilism. He rejected the view that liberty is self-determination, 'without regard to any extrinsecal Causes' (1707a: 34). It is, instead, merely 'a Power to do or forbear several Actions, according to the Determination of [the] Mind' (1707a: 35). It follows that liberty is consistent with Necessity, and 'ought not to be oppos'd to it, but only to Compulsion' (1707a: 38).

Collins embraced the doctrine of necessity in his first book ('no one action', he wrote, 'could possibly not happen' - 1707a: 36), but a full defence was presented only in *A Philosophical Inquiry Concerning Human Liberty*. There Collins argues as follows (1717: 57): (1) 'All … actions have a beginning' and (2) 'Whatever has a beginning must have a cause'. It follows that every action has a cause. Collins then claims that: (3) 'Every cause is a necessary cause'. It follows that every action has a necessary cause. Collins supports (3) by arguing against 'the *Epicurean System* of chance' (see Epicureanism §§4, 12).

Collins argues in the *Inquiry* that experience is no proof of a liberty incompatible with necessity. We deceive ourselves by considering actions of which we now repent. Because we are now in a repentant humour, we find no present cause of the action. But the circumstances we were in and the causes we were under made the action 'unavoidably determin'd'. It is this determination, in fact, that is a matter of experience: 'for are we not manifestly determin'd by pleasure or pain, and by what seems reasonable or unreasonable to us, to judge or will or act?' (1717: 24). Collins also argues that necessity is 'the sole foundation of morality and laws' (1717: iv). It is, for one thing, a presupposition of effective punishment, for if human beings were not necessary agents determined by pleasure and pain, the threat of pain could not motivate them. He even argues that a grasp of the very distinction between virtue and vice depends on being a necessary agent.

Collins often speaks against liberty, but his real target, as he sometimes makes clear, is liberty inconsistent with necessity. We have, as he emphasizes at the close of the *Inquiry*, 'a truly valuable *liberty* of another kind' (1717: 116) - the power to do as we will, or as we please. Had we this power or liberty in all things, he concludes, we would be omnipotent. Collins also admits there is a difference between the 'moral necessity' (determination by reason and the senses) to which human beings are subject - and the 'absolute, physical, *or* mechanical necessity' to which stones and clocks are subject. Throughout the *Inquiry*, Collins portrays the hypothesis of necessity as an opinion friendly to religion, and the belief in liberty inconsistent with necessity as atheistic. He claims that even 'most of those who assert *liberty* in words' - liberty inconsistent with necessity, that is - 'deny the thing, when the question is rightly stated' (1717: 111), an observation that anticipates Hume.

In his *Remarks upon a Book Entitled, A Philosophical Enquiry concerning Human Liberty* (1717), Samuel Clarke agreed that every action has a cause, but denied that every cause is a necessary cause. The cause of an action is the 'self-moving power' of the person. Motives and reasons *influence* action, but they do not cause it. Collins' final work on the topic, *A Dissertation on Liberty and Necessity* was published in 1729, after Clarke's death. He claimed that Clarke, in his criticisms of the *Inquiry*, simply assumed that the soul is a self-moving power (see Clarke, S. §2).

4 The immateriality and immortality of the soul

In *A Letter to the Learned Mr. Henry Dodwell* (1707), Collins took aim at Clarke's arguments for the immateriality and immortality of the soul. In *A Letter to Mr. Dodwell*, Clarke had argued that because a material thing is divisible, it cannot be an individual consciousness. A mind or individual consciousness must therefore be immaterial, and if it is immaterial, it is naturally immortal: it cannot be destroyed (or robbed of its essential powers) by any natural process. Collins made several objections. First, he claimed, Clarke simply assumes that thinking is an 'individual power' - a power that can belong only to an indivisible thing. But there are, Collins maintained, powers (such as the sweet smell of a rose) that belong to divisible things, and cannot be reduced to the sum or aggregate of the powers of their parts. Thinking may be such a power, and for all we know, a human being may be a system of matter 'fitly disposed' (as John Locke had put it) to think (see Locke, J. §5). Second, Collins asked, even if Clarke managed to show that an immaterial substance must continue to exist, what proof is there that it must continue to think?

Clarke replied to Collins' *Letter*, and Collins to Clarke's reply. (When the controversy ended, each author had contributed four pieces, in addition to the original statement of Clarke's case in his *Letter to Dodwell*.) The central point at issue was the interpretation and application of Clarke's thesis (offered in reply to the first objection above) that 'every Power or Quality, that is or can be *inherent* in any System of Matter, is nothing else than the Sum or Aggregate of so many Powers or Qualities *of the same kind*, inherent in all its Parts' (Clarke [1707] 1738 vol. 3: 759) (see Clarke, S. §2).

5 Analogical predication

In *A Vindication of the Divine Attributes* (1710), Collins argues against the proposal (made by William King in *Divine predestination and fore-knowledge* [1709]) that wisdom, goodness, justice and mercy are 'attributed to God in the same improper analogous Sense' (1710: 14) as parts or passions. Collins objects that if *all* of God's attributes are analogical, we cannot differentiate between theism and atheism. Nor can we make it our duty to imitate the divine perfections.

6 Biblical interpretation

William Warburton regarded Collins' *A Discourse of the Grounds and Reasons of the Christian Religion* (1724) as one of the most plausible arguments ever made against Christianity (Warburton [1738] 1765 vol. 5: 281). In *The Reasonableness of Christianity* (1695), Locke had put forward as the one essential doctrine of Christianity the belief that Jesus is the Messiah. In Part 1 of the *Grounds and Reasons*, Collins argues that it can be established that Jesus is the Messiah only if it can be shown that Jesus, as described in the Gospels, fulfils the Old Testament prophecies. But the Old and New Testaments, Collins argues, do not agree 'according to the literal and obvious sense' (1724: 39). The Old Testament must therefore be interpreted allegorically - 'in a secondary or typical, or mystical, or allegorical sense' (1724: 53). Collins insinuates that no reasonably controlled method of interpretation could arrive at the desired results. He mockingly presents a long list of rules meant to transform 'the mean literal sense of…words into a noble and spiritual sense' (1724: 59); the climactic rule permits a simultaneous change in the order of words, the addition of new words and the deletion of others.

In Part 2 Collins takes up William Whiston's proposal, in his *Essay towards Restoring the True text of the Old Testament* (1722), that the Old and New Testaments once agreed, and that the apostles argued literally. Since that time, however, the text of the Old Testament has been corrupted. Whiston proposes to establish the text as it stood in the days of Jesus and the apostles; Collins argues that this simply cannot be done (see Hermeneutics, Biblical).

7 Toleration

In *A Letter to the Reverend Dr. Rogers* (1727) Collins presents the following argument, among many others, for toleration:

(1) I judged the Christian religion true and joined the Church of England.
(2) I also judged that if I resided in Spain or Scotland, it would be my duty to worship God publicly, according to the way of the Church of England, and that the magistrate ought to protect me in this.

Collins does not infer the judgment in (2) from the judgment in (1). But (2) is, he suggests, a natural accompaniment of (1). And this suggests that magistrates in England should extend the same toleration to Spanish Catholics or Scottish Presbyterians that those who embrace the Anglican Church would expect from magistrates in Spain or Scotland (see Toleration; Latitudinarianism).

KENNETH P. WINKLER

List of works

Collins, A. (1707a) *An essay concerning the use of reason in propositions, the evidence whereof depends upon human testimony*, London.(Argues for the authority of reason in matters of religion.)

Collins, A. (1707b) *A letter to the learned Mr. Henry Dodwell; containing some remarks on a (pretended) demonstration of the immateriality and natural immortality of the soul, in Mr. Clarke's answer*, London; *A reply to Mr. Clarke's defence of his letter to Mr. Dodwell*, London, 1707; *Reflections on Mr. Clarke's second defence of his letter to Mr. Dodwell*, London, 1707; and *An answer to Mr. Clarke's third defence of his letter to Mr. Dodwell*, London, 1708, in *The Works of Samuel Clarke*, vol. 4, London, 1738, 719-909; repr. New York and London: Garland, 1978.(On Samuel Clarke's proofs of the soul's immateriality and immortality. Clarke's *Works* includes both sides of the controversy.)

Collins, A. (1710) *A vindication of the divine attributes*, London: H. Hills.(A criticism of William King's analogical theology.)

Collins, A. (1713) *A discourse of free-thinking, occasion'd by the rise and growth of a sect call'd free-thinkers*, London; repr. New York: Garland, 1976.(Collins' defence of freethinking.)

Collins, A. (1717) *A philosophical inquiry concerning human liberty*, London: R. Robinson; repr. as *Determinism and Free Will*, ed. J. O'Higgins, The Hague: Martinus Nijhoff, 1976.(Argues that liberty is compatible with necessity. The modern edition contains a detailed introduction and notes.)

Collins, A. (1724) *A discourse of the grounds and reasons of the christian religion*, London; repr. New York: Garland, 1976.(Contends that Jesus cannot be shown to fulfil Old Testament prophecies.)

Collins, A. (1727) *A letter to the reverend Dr. Rogers on occasion of his eight sermons concerning the necessity of divine revelation*, London.(Argues in defence of toleration.)

Collins, A. (1729a) *A dissertation on liberty and necessity*, London: J. Shuckburgh.(A reply to Samuel Clarke's criticisms of 1717.)

Collins, A. (1729b) *A discourse concerning ridicule and irony in writing*, London: J. Brotherton; repr. Los Angeles, CA: William Andrews Clark Memorial Library, University of California, Los Angeles, 1970.(Defends the use of ridicule, irony, mockery, and raillery in writing on religion; observes that defenders of the established church often resort to it.)

Colour and qualia

There are two basic philosophical problems about colour. The first concerns the nature of colour itself. That is, what sort of property is it? When I say of the shirt that I am wearing that it is red, what sort of fact about the shirt am I describing? The second problem concerns the nature of colour experience. When I look at the red shirt I have a visual experience with a certain qualitative character - a 'reddish' one. Thus colour seems in some sense to be a property of my sensory experience, as well as a property of my shirt. What sort of mental property is it?

Obviously, the two problems are intimately related. In particular, there is a great deal of controversy over the following question: if we call the first sort of property 'objective colour' and the second 'subjective colour', which of the two, objective or subjective colour, is basic? Or do they both have an independent ontological status?

Most philosophers adhere to the doctrine of physicalism, the view that all objects and events are ultimately constituted by the fundamental physical particles, properties and relations described in physical theory. The phenomena of both objective and subjective colour present problems for physicalism. With respect to objective colour, it is difficult to find any natural physical candidate with which to identify it. Our visual system responds in a similar manner to surfaces that vary along a wide range of physical parameters, even with respect to the reflection of light waves. Yet what could be more obvious than the fact that objects are coloured?

In the case of subjective colour, the principal topic of this entry, there is an even deeper puzzle. It is natural to think of the reddishness of a visual experience - its qualitative character - as an intrinsic property of the experience. Intrinsic properties are distinguished from relational properties in that an object's possession of the former does not depend on its relation to other objects, whereas its possession of the latter does. If subjective colour is intrinsic, then it would seem to be a neural property of a brain state. But what sort of neural property could explain the reddishness of an experience? Furthermore, reduction of subjective colour to a neural property would rule out even the possibility that forms of life with different physiological structures, or intelligent robots, could have experiences of the same qualitative type as our experiences of red. While some philosophers endorse this consequence, many find it quite implausible.

Neural properties seem best suited to explain how certain functions are carried out, and therefore it might seem better to identify subjective colour with the property of playing a certain functional role within the entire cognitive system realized by the brain. This allows the possibility that structures physically different from human brains could support colour experiences of the same type as our own. However, various puzzles undermine the plausibility of this claim. For instance, it seems possible that two people could agree in all their judgments of relative similarity and yet one sees green where the other sees red. If this 'inverted spectrum' case is a genuine logical possibility, as many philosophers advocate, then it appears that subjective colour must not be a matter of functional role, but rather an intrinsic property of experience.

Faced with the dilemmas posed by subjective colour for physicalist doctrine, some philosophers opt for eliminativism, the doctrine that subjective colour is not a genuine, or real, phenomenon after all. On this view the source of the puzzle is a conceptual confusion; a tendency to extend our judgments concerning objective colour, what appear to be intrinsic properties of the surfaces of physical objects, onto the properties of our mental states. Once we see that all that is happening 'inside' is a perceptual judgment concerning the properties of external objects, we will understand why we cannot locate any state or property of the brain with which to identify subjective colour.

The controversy over the nature of subjective colour is part of a wider debate about the subjective aspect of conscious experience more generally. How does the qualitative character of experience - what it is like to see, hear and smell - fit into a physicalist scientific framework? At present all of the options just presented have their adherents, and no general consensus exists.

1 Physicalism and objective colour

The question 'What sort of property is the redness of the shirt?' is sensible only against a background of assumptions regarding what counts as an informative answer. Otherwise, the following naïve response seems appropriate. Colour is one of the features physical objects have, and red is a type of colour. What else is there to

say? What makes the question substantive, however, is the background assumption of the doctrine of physicalism.

Physicalism is a doctrine accepted by a wide variety of philosophers, despite wide disagreement about its detailed characterization. There are two basic tenets: (1) that there is a privileged level of basic physical properties, its precise inventory being the business of physical science to determine; and (2) that all causal transactions in nature occur by virtue of mechanisms that are ultimately realized by the properties of this basic class. This doctrine is sometimes expressed by the slogan, ‘no change without a (basic) physical change’ (see Materialism in the philosophy of mind; Supervenience of the mental).

Acceptance of physicalism generates a problem about colour in the following way. The colour of my shirt - its being red - has causal influence; most notably, on the visual experiences of sentient beings. By the second principle of physicalism there must be physical mechanisms that mediate this influence. So how do these mechanisms relate to the colour?

There seem to be four possible answers. First, colour is itself a basic physical property, akin to mass, charge, charm and the like. Second, colour is reducible to other physical properties, in something like the way that heat is reducible to mean kinetic energy or water is reducible to H_2O (see Reductionism in the philosophy of mind). Third, there is no natural physical property with which to identify colour: colours are mind-dependent properties in the sense that they can only be characterized by reference to their effects on human visual systems. Finally, colours are not real properties of objects at all: in a sense they are an illusion (see Colour, theories of; Property theory).

The first alternative is clearly a non-starter, since colour is not a basic physical property. There is controversy about the second. To explain the controversy, we must review some basic facts about colour vision. What we normally think of as perceived colour is a combination of three properties: hue, brightness and saturation. Hue (essentially the shade of colour itself) is determined by the wavelength composition of the light hitting the eye; brightness is determined by the relative intensity of the light; and saturation is a matter of how much hue relative to white light there is in the stimulus.

Now, it might be thought that a specific colour could be identified with light of a specific wavelength, intensity and saturation. Then the colour of a physical object could be identified with a tendency to reflect just that composition of light. However, it turns out that bundles of light with quite different distributions of wavelengths can produce the same effect on the visual system and therefore are perceived as the same colour. (Such distributions are called ‘metamers’.) Also, there is the phenomenon of colour constancy. As illumination changes, say from bright outdoors to indoors, or noon to late afternoon, the composition of the light reflected from my red shirt changes. Yet it continues to look red throughout. One standard explanation of colour constancy is that the visual system takes changes of illumination into account by comparing the light reflected from many objects at once, thus using the contrast as a major determinant of perceived colour. But this makes the identification of colour with any property of the light reflected from an object quite complicated, if not hopeless.

In response to this problem, David Hilbert (1987) proposes that we identify colour with the complex, but quite objective, property of ‘spectral reflectance’. An object’s spectral reflectance is a function that takes specific distributions of light contained in illuminants as input and specific distributions of light reflected as output. He argues that it is precisely this property that is preserved in cases of colour constancy. What we perceive when we perceive the shirt as red throughout changes of lighting conditions is its surface spectral reflectance. There are various problems with this view, the most notable being the problem of metamers. As mentioned above, two very different light distributions, even against the same background illumination, can yield the same perceived colour. Yet, in Hilbert’s view, since the two objects reflecting these two different distributions have different spectral reflectances, they must count as differently coloured. This seems quite counterintuitive, especially if the background illumination in question is broad daylight. (Hardin (1988) dismisses the spectral reflectance view largely for this reason. Hilbert (1987) responds at length to the objection, and the interested reader should consult his discussion.)

In view of the difficulties with the second alternative, it might be thought that colour is best thought of as a disposition on the part of objects to cause certain experiences in us. So what makes the shirt red is its disposition, however grounded in its physical properties, to cause a normal human observer, under normal conditions, to have a

reddish visual experience. (The historical roots of this position can be found in Locke's discussion of primary and secondary qualities; see Primary-secondary distinction; Locke, J. §4.) Note that on the dispositional view, colour is a real, but mind-dependent property of objects. That is, objects are really coloured, though their being so is dependent on properties of us.

Hardin (1988) disputes the dispositional view on the grounds that there is no principled analysis of the phrases 'normal conditions' and 'normal human observer'. Thus there is no unequivocal way to attribute colours to objects, since as we change observer and conditions we change the object's colour. On his view the appropriate locus of colour attribution is experience: there are chromatic experiences, but no coloured objects. In our terms, there is only subjective colour, no objective colour.

2 Subjective, 'qualitative' colour

The puzzle concerning subjective colour is an instance - perhaps the most discussed instance - of the general puzzle concerning the qualitative, or phenomenal, character of conscious mental states: the puzzle of 'qualia'. We will continue to restrict our attention to colour experience, but most of the positions and arguments we review can be applied to the more general issue of phenomenal experience as a whole. Moreover, when it comes to visual experience, colour provides the most compelling challenge to an account consistent with physicalism. Indeed, we now need to ask the same question about subjective that we asked about objective colour: what sort of physical property could it be?

One obvious way of sorting properties is to distinguish intrinsic from relational properties. To a first approximation, intrinsic properties are those that an object possesses in virtue of conditions wholly within the object. Relational properties are those that an object possesses in virtue of its standing in some relation to other objects. So, for instance, my body's mass is an intrinsic property, whereas its weight is relational, since it depends on my body's location relative to the gravitational field generated by another object. (I weigh less on the moon than on the earth, though my mass is the same.)

Let us call the reddish qualitative character of my visual experience of the shirt 'subjective red'. Is subjective red an intrinsic property of my experience? At first blush, it certainly seems to be. But, given the constraints of physicalism, if subjective red is an intrinsic property of my experience, and if my experience enters causal transactions with other states (or events) in virtue of its qualitative character, then subjective red must be somehow reducible to, or composed of, a physical property of my nervous system.

3 The identity theory and its problems

This latter line of reasoning has led many to what has been called the 'central state identity theory'. On this view, an experience is identifiable with a neural state, and its (intrinsic) properties are ultimately neural in character (see Mind, identity theory of). Three sorts of challenges have been mounted against this identification: (1) the conceivability argument, (2) the multiple-realizability argument, and (3) the knowledge argument.

According to the first, since it seems conceivable that one could be having an experience of a reddish sort but not be in the neural state in question, the experience cannot be the same as the neural state. However, put so baldly, this argument is clearly fallacious. It is conceivable that water might not have been H_2O, but that is no reason to deny that it is in fact identical to it (see Intentionality; Propositional attitude statements). However, the conceivability argument seems to many to be getting at something not so easily dismissed, and this is brought out by considering the second argument, about multi-realizability: subjective red cannot be identical to a neural state because it seems possible that there could be creatures with a different sort of physical constitution (say, Martians, or robots) that could nevertheless experience reddish visual sensations like ours. This seems more interesting than mere conceivability, since the possibility seems to survive the discovery that, among all the instances we have observed, subjective red always happens to be realized by a certain neural state. This does not seem to be the case with, for example, water and H_2O: if all the water we have observed is H_2O, that seems to be a good reason to think that all water is (see Kripke 1980; Essentialism).

The last argument, the knowledge argument, is due to Frank Jackson (1982). If subjective red is a physical property, then if one knows all the relevant physical facts pertaining to colour vision one will know all there is to know about subjective red. Imagine Mary, a vision scientist who possesses the complete physical theory of colour

vision, but who has lived in a totally achromatic environment her entire life; she has only seen the world in black and white. Upon release from this restricted environment, she encounters a ripe tomato, and exclaims, 'So that's what red looks like!'. It seems she has learned something new, and yet, Jackson argues, if physicalism is true she should already have known all there was to know about colour experience. Hence, subjective red is not a physical property.

Now, one reply to this argument is the same as to the conceivability argument. 'Knowledge', another intentional term, is referentially opaque: the fact that Mary knows all the physical facts and yet cannot recognize subjective red from its physical description does not show that subjective red is not identical to a physical property; after all, the fact that she might know all the physical facts about H_2O without recognizing that it is water does not show that water is not H_2O. Mary may, in one sense, know everything there is to know when she learns all the physical facts, just not under every possible description. But that constitutes no problem for physicalism.

Still, however, many philosophers feel that these replies are missing the point. What provides plausibility to the three arguments is that appeal to the neural properties of one's visual state does not seem to *explain* its qualitative properties. The fact that these neurons are firing in this way does not really explain the shirt's looking 'reddish'. This is known as the 'explanatory gap' argument (see Levine 1983, 1993; Explanation).

It could be put this way: once we discover the chemical composition of water, and know various chemical laws governing the states and interactions of physical substances, we can explain the features of water that we initially used in picking it out. For instance, we can explain why it freezes and boils at the temperatures it does, why it is necessary for life, and a host of its other properties. In fact, it is not really conceivable that something could be H_2O and yet fail to manifest these various properties, at least so long as we fix basic chemical laws. This seems to be what at least the conceivability and knowledge arguments are getting at: that the physical facts do not 'upwardly necessitate' facts about qualitative experience in the way that chemical facts necessitate facts about water. No matter how detailed our knowledge of the physical mechanisms by which neurons transmit their impulses from one to the other, we are still left with the question of why all this electrochemical activity should constitute an experience with a reddish (as opposed to a greenish, say) qualitative character. It still seems quite conceivable that such electrochemical activity should occur and yet not the experience of subjective red, and this residual conceivability is a manifestation of the explanatory gap. To put the matter in terms of the knowledge argument, the fact that Mary would learn something new upon emerging from her achromatic world is evidence that the physical theory of colour vision does not really explain the qualitative character. Even if she knew the meaning of ordinary 'red' she could not deduce from the rest of her knowledge that tomatoes look red (in the way that she could deduce that water freezes at $32^\circ F$).

One might object that appeals to neurophysiology can indeed provide an explanation of subjective red. For one thing, if we were to find a stable correlation between subjects' reports of reddish sensations and their occupying certain neurophysiological states, then we could predict the occurrence of these sensations from knowledge of their brain states. For another, knowledge of the neurophysiological properties explains the mechanisms by which subjective red performs its cognitive functions. Colour perception involves selective sensitivity to fairly complicated properties of the light reflected from physical surfaces, and we now know a lot about how that sensitivity is implemented in neural hardware.

The problem with the first consideration is that in place of a genuine explanation all we are given is a brute correlation. I may be able to predict with perfect confidence that when someone occupies this particular neurophysiological state they are having a reddish sensation, but my ability to make this prediction does not manifest an understanding of why this brain state should go with reddish, and not bluish or greenish sensations. Brute facts are just that; they are not explicable. Moreover, they do not support counterfactuals: how are we to judge whether something lacking a specific physical property we possess really would not be having a reddish experience? What could satisfy us about the modal claim that not only are reddish experiences correlated with a certain neural state *in fact*, but*must* be so correlated?

Of course sometimes we admit that certain facts are brute facts; for instance, the value of the gravitational constant, the basic laws of physics, and the like. But notice it is a methodological assumption of current scientific practice, a corollary of physicalism, that only at the basic physical level are brute facts to be found. The idea that

something as complicated as the brain should just give rise to reddish experience, and there be no explanation of this fact, is inconsistent with fundamental Physicalist assumptions.

If there is any hope for explaining subjective colour within a Physicalist framework, it would seem to depend on the second consideration: showing how the neurophysiological states of the brain provide the mechanisms by which colour sensations perform their cognitive functions. But to make this work it is necessary to analyse subjective colour in terms of its function, for otherwise explaining that function would not count as a full explanation of subjective colour itself. In other words, we need to abandon the treatment of subjective colour as an intrinsic property of sensation, and treat it instead as a relational, or functional, property.

4 Functionalism

Functionalism is the view that mental states are definable in terms of their causal roles, their causal relations with stimuli, behaviour and other mental states (see Functionalism). Thus, arguably, something is a belief if and only if it is the result of perception or reasoning and the cause, with desires, of action. So a state would be an experience of subjective red just in case it was normally caused by viewing red things, it tended to cause judgments to the effect that something was red, and it generally related to other mental states - in particular through similarity judgments - in the way that is typical of experiences of red. Let us call the functional role in question ‘functional red’.

A more specific form of the functional/relational approach is to treat qualitative states as essentially representational, and qualitative content as representational content. The idea is this. When I have a reddish experience I am in the state of representing the object I perceive as having a certain property, in this case the property of being red. Immediately, of course, the question arises how to distinguish colour experience from mere colour belief. The standard reply is to appeal to the special functional role of the visual system, for example, by attributing to it some distinctive representational system all its own. The point is that to have a reddish experience is to represent an external object as red in this special visual way. This is a relational theory since subjective red’s identity is determined by its representational content, which is a matter of its relation to external objects, and it is a functional theory, since the particular functional organization of the visual system provides the basis for distinguishing experience from mere judgment.

One thorny problem for the representational approach involves the alleged representational content of the sensation. Above we said that subjective red is a representation that some object is red. But what is ‘being red’? As our earlier discussion showed, it is not easy to specify what property objective redness is, so it is correspondingly difficult to specify what the representational content of subjective red is supposed to be. There are various ways a representationalist can respond. If one believes that colour is identifiable with a spectral reflectance function, then that could be the content of the sensory representation. If, however, one denies the existence of objective colour, one could say that our sensory systems represent objects as having a property that they in fact do not have. This is the so-called ‘error theory’. Finally, one might be subjectivist about the content of subjective red itself. That is, one could say that a reddish experience is a report from the visual system concerning its own state - a way of saying, ‘I’m experiencing redly now’ (see Mental states, adverbial theory of).

Note that it is no objection to the first proposal that the alleged content has a complex theoretical structure and therefore could not plausibly be attributed to our sensory system. There are many representations we employ which in their internal structure are relatively simple and yet they refer to properties or objects which have a complex structure, and about which experts possess sophisticated theories. Take the well-worn example of water. According to most philosophers of language and mind, when I think about water I am thinking about a substance with the structure H_2O. But of course I do not have to know this, and it certainly is not plausible to claim that my mental representation of water contains representations of hydrogen and oxygen. Similarly, subjective red could function to detect, or register, a certain complicated property of an object’s surface without itself possessing complex structure.

5 Objections to functionalism

The basic objection to a functionalist account of subjective colour, or of any qualitative experience, is that it just seems intuitively plausible that functional red and subjective red could come apart. The mismatch goes in both

directions. That is, according to the famous absent and inverted qualia hypotheses, it seems quite possible that a creature could satisfy the conditions for functional red even though not experiencing subjective red, or, for that matter, having any qualitative experience at all. On the other hand, it also seems quite possible that a creature could experience subjective red even though most of the causal relations it normally maintains were absent (this is less emphasized in the literature).

An example of the first sort of problem is the famous ‘inverted spectrum’ thought experiment. As we noted above, colour experience is a function of three basic features: hue, brightness and saturation. Colour quality space can be modelled then as a three-dimensional solid; in fact, a cone. The vertical dimension represents brightness, the horizontal represents saturation, and the circular dimension represents hue. Given this model, there seems to be a mapping of points in the space onto their complements around an axis that bisects the cone through the middle. Reds would be mapped onto greens, blues onto yellows, and so on. The resulting cone would be isomorphic to the original in the sense that all the distance/similarity relations among points would be maintained.

Given this characterization of an inversion, take two creatures, one of whom has a colour quality space described by the original cone and the other of whom has one described by the inverted cone. If we are just looking at the relational properties - those involving causal relations to external stimuli, internal mental states, and behaviour - it seems that the two creatures would be functionally isomorphic. Yet, when looking at a red fire engine one would be having a reddish experience and the other would be having a greenish one. In other words, while they would both satisfy the criteria for functional red, one would be having an experience of subjective red and the other of subjective green. So, subjective red cannot be identical to functional red.

The ‘absent qualia’ hypothesis represents an even more extreme possibility. Ned Block (1980) asks us to imagine the entire nation of China (or any similarly large group of individuals) organized, say, by telephone, so as to realize the functional organization of a human brain. Let us also imagine that this vast network is connected to a robot which has a video camera for an ‘eye’. When the robot is stimulated by light from a fire engine the network will go into a state of functional red, by hypothesis. Yet, it seems quite bizarre to claim that the robot, the network, or the system comprising both, is having a qualitative experience. Thus we have a case of functional red without subjective red (or any qualitative character at all).

An example of subjective red without the normal causal connections could occur if someone’s normal functioning were disturbed, so that various relations between their colour experience and memory, belief and the like no longer held. It seems possible that this could happen while the qualitative character of their experience remained unchanged. One concrete case of this is colour blindness. The fact that someone cannot distinguish red from green obviously affects the structure of their colour space, yet it is not obvious that this makes their experiences of blue any different from mine.

6 Replies

There have been three basic responses to these anti-functionalist arguments. The first is to grant their cogency and claim that for experiences such as subjective red, as opposed to cognitive states such as belief, functionalism is wrong and the traditional identity theory is right. But then one must confront the objections to that theory discussed above: the multiple-realizability argument and the explanatory gap.

The second sort of response is to attempt to undermine the intuitive resistance to a relational account represented by the absent and inverted qualia hypotheses. Numerous such attempts have been made, but we will focus on two related strategies in particular: what might be called the ‘asymmetries’ strategy and the ‘subtle role’ strategy. In the end they are both problematic, but they represent serious attempts to meet the challenge and their problems are instructive.

The basic idea behind the asymmetries strategy is to argue that an appropriately chosen and sufficiently rich relational description can uniquely identify a type of qualitative character, and thereby get around the sorts of counterexamples just discussed. Consider the inverted spectrum argument. As presented above, it seems to make the assumption that there exists a natural axis of symmetry dividing the colour cone. However, there is empirical evidence to the effect that this is not so (see Colour, theories of).

First, there is the question of the location of the primaries. It seems evident that some hues are experienced as

combinations of others, while some seem not to be. Contrast a pure red or green with orange or purple. One might have thought that pure examples of each of these primaries would occupy points in the three-dimensional colour solid equidistant from the origin, representing equal amounts of brightness and saturation, and equidistant from complex hues. But not so. Yellow, for instance, occupies a point of higher perceived brightness than do the other primaries. Also, some primaries occupy a larger region than do others; that is, there are more steps to be taken before we describe what we see as a combined hue. Furthermore, there is the anomaly of brown, which results from darkening yellow, yet is not thought of as merely dark yellow but another hue altogether. The point is that if you were to invert along the red-green and blue-yellow axis, it does not look as if all the relational judgments would be the same. Normals would consider dark and light blues to have the same hue, but inverts would not. Normals and inverts would differ in when they considered hues to be combinations, as opposed to primaries. Functional identity between normals and inverts could not be maintained. Hence, they would not be functionally identical to us, and spectrum inversion would not constitute a counterexample to functionalism. (See Harrison 1973; Clark 1993; Hardin 1988 for arguments along these lines.)

The second, ‘subtle role’ strategy is aimed more at the absent qualia hypothesis. The idea here is to attack the notion that a creature could be functionally identical to us and yet lack qualia by demonstrating that qualitative character is itself essential to normal functioning. Van Gulick (1993) notes that there is some evidence, for example, from blindsight cases - in which a patient claims not to see anything within a certain region of their visual field and yet can correctly ‘guess’, upon prompting, whether or not something is there - that consciousness is necessary for carrying out certain functions (see Consciousness §7; Unconscious mental states). For instance, blindsight patients tend not to initiate action with respect to the objects that they can passively detect in their blind field. If, as such cases suggest, consciousness is essential to the performance of certain functional roles, then it is not possible for a non-conscious state to play the same functional role. Hence, absent qualia are not possible.

We said above that there are problems with both strategies. With respect to the asymmetries strategy, there are two basic objections. First, even if the geometric space that characterizes our colour experience is in fact asymmetrical in the way described above, this seems to be a contingent feature of it. Why should this matter? So long as it is not demonstrated that it is essential to qualitative experience that it be immune to inversion, we have no reason to believe that all forms of qualia will have this feature. But if any form of qualitative experience is susceptible to inversion, functionalism is in trouble.

Moreover, as suggested earlier by the case of red-green colour blindness, there could easily be cases of individuals whose colour experience is somewhat, but not completely, different from our own. Suppose that theirs is symmetrical, and therefore subject to inversion. Would it not make sense to say that when such a person looked at a red fire engine they were having an experience that was more like our subjective red than, say, our subjective green? But, if inversion were possible for them, we could not say this solely on the basis of their functional organization.

The second problem with the asymmetrical approach is that it does nothing to address the absent qualia hypothesis. Suppose that any inversion of primaries would be detectable. Still, given cases like Block’s China-head, it seems possible that a creature could realize a structure onto which the complete set of similarity relations definitive of the colour solid could be mapped, and yet there be *nothing* it is like to be that creature. Addressing the inverted qualia argument alone does not save functionalism.

The ‘subtle role’ strategy is, of course, specifically addressed to absent qualia. But here too there is a problem. Suppose we have to grant that there may be jobs, or roles, that only qualitative states can fill. That still does not mean that filling that role is what it is to be a qualitative experience. In fact, that very way of putting it - that being qualitative is essential, or necessary to playing the role - seems to imply just the reverse; that being qualitative is one thing, playing the role quite another. Suppose it turned out that being red was essential to some plant’s playing the ecological role it played; nothing that was not red could do it. We would not say that being red is to play that role, but rather that being red is what makes the plant in question especially suited to play that role. It seems that the same goes for subjective red - the qualitative experience of seeing red - in the scenario Van Gulick envisaged.

Nor is it clear how the ‘subtle role’ strategy addresses Block’s counterexample concerning the nation of China. Either one would have to admit that the entire nation experienced subjective red, or one would have to argue that the lack of qualitative character in this case posed an insuperable obstacle to realizing the relevant functional

description. Both positions are difficult to defend. However, some (see Lycan 1987) have argued that there are other constraints - for instance, extremely fine-grained functional descriptions couched in teleological terms - that would rule out the nation of China as a legitimate realization (see Functional explanation).

In discussing the problems for functional accounts of colour qualia, we have not distinguished among various forms of functionalism. In particular, we have not addressed the representational version of functionalism, according to which colour qualia are functionally specific forms of representations of colour properties. It is sufficient to note here that the absent and inverted qualia hypotheses cause problems for this version of functionalism as much as any other. For suppose that an inverted spectrum is possible. Then two states could differ in their qualitative character and yet carry the same information concerning the reflectance properties of distal stimuli. Or, if absent qualia are possible, then a state could carry information concerning the reflectance properties of a distal stimulus and yet there be nothing at all it is like to occupy the state. If either case is possible, one cannot identify qualitative character with the representation of such properties (see Semantics, informational).

7 Eliminativism

We have seen that functional/relational analyses of colour qualia face serious difficulties. We have also seen that treating colour qualia as intrinsic properties also encounters a serious obstacle, in the form of the explanatory gap. Of course there are possible replies to these difficulties, and many contemporary philosophers hold one or the other of these views. Yet, the persistence of objections to the various accounts of qualia has led some philosophers to embrace eliminativism about subjective colour (whether or not they, like Hardin, are eliminativists about the objective sort). That is, they see the philosophical problem of qualia as our attempting to identify a real phenomenon in the world which corresponds to a conception to which no real phenomenon does, nor even could, correspond. Belief in qualia is something like belief in ghosts. Just as we do not bother to find some real phenomenon to serve as the referent of our idea of a ghost, so too we should abandon the idea that a real phenomenon could serve as the referent of our idea of subjective red (see Eliminativism).

Eliminativism is quite naturally joined to the representational position just described. No one literally denies that we experience sensations of colour. That the fire engine looks red to me is a genuine fact. However, the eliminativist teases apart what is genuine about this fact from what is illusory in the following manner. That I see, and therefore judge, the fire engine to be a certain way, is undeniable. But it is wrong to infer from my perceptual judgment concerning the surface of the fire engine to the existence of a colour-like property of my experience itself - a colour *quale*. It is the existence of this inner property - around which inversion and absence puzzles take hold - that the eliminativist denies.

A major source for eliminativist sentiment is Wittgenstein’s famous attack on the coherence of any notion of inner experience that did not manifest itself in outwardly observable behaviour (see Criteria; Private language argument). While Wittgenstein had many targets in mind with his ‘private language argument’ - his argument against the possibility of a language that only one person could possibly understand - certainly the idea that I could introspect and discover qualia as properties of my inner experiences was one of them. A number of philosophers have extended this Wittgensteinian critique, most notably Daniel Dennett (1991). As Dennett characterizes them, believers in qualia are tied to a picture of the mind as a theatre (the ‘Cartesian theatre’), in which mental entities are on display before the mind’s eye. He has coined the term ‘figment’ to capture the unjustified inference from the reality of colours as properties of physical objects to the reality of colour qualia as properties of internal states.

Suggestive as this diagnosis of the problem of colour qualia is, it alone does not really constitute an argument in favour of eliminativism. However, various further arguments have been presented in the recent literature. First, the believer in qualia is accused of allegiance to a dualist metaphysics. Second, qualia are disparaged as posits of common-sense psychology, a theory that, like many common-sense theories of the world, must give way before its more rigorous and detailed scientific competitors. Third, thought experiments like the inverted and absent qualia hypotheses are attacked as internally incoherent. Finally, belief in qualia is alleged to lead to unsavoury sceptical consequences. For instance, if someone could be functionally identical to me without having qualia, how do I know I really have them? (Of course some of these same arguments could serve to support a reduction of qualia to functional states, rather than their elimination. The line between eliminativism and reductionism, either of the functional or neurophysiological variety, is not always easy to draw.)

Advocates of colour qualia have responded to these arguments. Those who do not straightforwardly embrace dualism deny that their position entails it. Qualia, on their view, are not posits of an outmoded theory, but among the primary data that any adequate psychological theory must explain. The discussion above demonstrates how hard it is really to undermine the inverted qualia hypothesis. As for the charge of scepticism, many dismiss it as just that. Sceptical worries attach to most phenomena, they argue. But whether or not these replies succeed, eliminativist challenges of the sort just described will find adherents so long as a truly explanatory connection between qualitative character and neurophysiological or functional organization is still lacking.

Colour, theories of

The world as perceived by human beings is full of colour. The world as described by physical scientists is composed of colourless particles and fields. Philosophical theories of colour since the Scientific Revolution have been driven primarily by a desire to harmonize these two apparently conflicting pictures of the world. Any adequate theory of colour has to be consistent with the characteristics of colour as perceived without contradicting the deliverances of the physical sciences.

Given this conception of the aim of a theory of colour, there are three possibilities for resolving the apparent conflict between the scientific and perceptual facts. The first is to deny that physical objects have colours. Theories of this kind admit that objects appear coloured but maintain that these appearances are misleading. The conflict is resolved by removing colour from the external world. Second, it might be that colour is a relational property. For an object to possess a particular colour it must be related in the right way to a perceiver. One common version of this view analyses colour as a disposition to cause particular kinds of perceptual experience in a human being. Since the physical sciences deal only with the intrinsic properties of physical objects and their relations to other physical objects and not their relations to perceiving subjects, the possibility of conflict is removed. A third possible response is to maintain that colour really is a property of external objects and that the conflict is merely apparent. Some theories of this form maintain that colour is identical to a physical property of objects. Others maintain that colour is a property that physical objects possess over and above all their physical properties. Philosophical discussions of colour typically take the form of either elaborating on one of these three possibilities or attempting to show more generally that one of these three types of response is to be preferred to the others.

1 Eliminativist theories of colour

The association between atomistic metaphysics and the denial that colour has any place in the external world is both ancient and common. It can be found in authors as widely separated in time and other views as Democritus and Galileo. Although metaphysics is no longer atomistic in a strict sense, many contemporary scientists hold similar views about the absence of colour from the external world. Colours as perceived are commonly seen by those acquainted with scientific metaphysics to have features that preclude all attempts at the identification of colour with a physical property of external objects.

Once colour has been excluded from the external world there still remains the question of which objects, if any, possess colour. One possible answer to this question is to maintain that colours are genuine properties of some perceptual experiences. This view is a kind of phenomenalism with regard to colour (see Phenomenalism). Although colour phenomenalists maintain that no tomato is red, strictly speaking, it may be that the visual experience obtained by looking at a ripe tomato in good light genuinely does possess the property of being red (Jackson 1977). Something like this answer combined with a reductive account of mental properties may explain the repeated claims by visual scientists of the last two centuries that colours are properties of the brain. This form of subjectivism requires a commitment to the existence of *qualia* or sense-data: in other words, intrinsic properties of visual experience to which we have unmediated conscious access (see Qualia).

Alternatively, it may be argued that nothing, including visual experience, has colour. C.L. Hardin (1988) has argued, first, that there are essential properties of colour as perceived that no physical property possesses, then further that there are no mental items which could be the bearers of colour. The upshot is that although there are objects which *appear* coloured, there is nothing that *is* coloured.

The main difficulties faced by the various forms of colour eliminativism all derive from its failure to produce an adequate resolution of the apparent conflict between the scientific world and the perceptual world. Our visual experience is an experience of coloured objects. The external focus of our visual experience is also reflected in much of our thought and talk about colour. All forms of colour subjectivism are forced to maintain that our visual experience is profoundly misleading and most of our talk and thought about colour, if taken literally, profoundly confused. Colour subjectivism removes any possibility of conflict between perception and science by either moving the location or denying the reality of the world as we perceive it. Colours are properties of visual experience mistakenly projected in perception and thought onto external objects. The main motivation for attributing such widespread confusion to our ordinary thought and language is the failure of any less radical

account successfully to accommodate all the relevant facts.

2 Relational theories of colour

One motivation for adopting eliminativism about colour is the obvious dependence of perceived colour on the characteristics of our visual system. Organisms whose visual systems differ from ours will divide the spectrum in different ways. Objects that look the same in colour to us may look very different in colour to organisms whose sensory apparatus differs in certain ways from ours. In general, neither the categories nor the similarity relations that arise from human colour vision map in a straightforward way onto any physical property. Two coloured surfaces that are an exact perceptual match can be physically very different and, in general, similarity in perceived colour (of whatever degree) is no reliable guide to similarity in any interesting physical property. Eliminativism is not, however, the only possible theory of colour capable of accommodating these facts. Rather than eliminating colour from the world, relational theories of colour take colour to consist in a relation between the external perceived object and the perceiving subject.

The most common form of relational theory has taken colours to be dispositions or powers to cause characteristic kinds of perceptual experience. Dispositional theories of colour date back at least to the seventeenth century and continue to have widespread currency among philosophers. The most famous early exponent of this view of colour is John Locke (see Locke, J. §§3-4; Primary-secondary distinction §1). According to a theory of this kind, an object is red, for example, if and only if it has the power or disposition to cause a characteristic kind of experience in an appropriately situated human being.

Colours are to be thought of, according to relational theories, as analogous in important respects to physical properties like solubility and more precisely to qualities like nutritiousness or poisonousness. A substance is poisonous, for example, if it causes degradation in bodily function if taken into the body. Whether or not a substance is poisonous depends on what kind of organism is under consideration. Some substances cause bodily harm to some organisms while being harmless or even beneficial to other organisms. Thus the very same substance can be poisonous to one kind of organism and nutritious to another. Whether or not a substance brings about degradation in bodily function can also depend on the circumstances in which it is ingested. Substances that are harmless if taken by themselves can be poisonous if taken in conjunction with other substances. According to relational views of colour, an object can be red to one kind of perceiver and green to another in virtue of possessing exactly the same intrinsic physical characteristics. What matters is the kind of causal effect the object has on the perceiver, which depends in turn on the characteristics of the perceiver's visual system. The kind of effect an object has on a perceiver can also vary with changes in the viewing conditions, notoriously the character of the illumination, and consequently the colour of an object can change with viewing conditions. According to relational views of colour, no object has any particular colour if considered independently of how it is related to perceiving organisms.

One difficulty with relational views of colour is that they seem on the surface to be incompatible with the way we ordinarily talk about colours. We often make claims like 'that tomato is red' without offering any further explanation of who it is red for and in which circumstances. In addition, if someone were to claim of a beautiful ripe tomato that it is black, the ordinary response would be denial or puzzlement in spite of the fact that there are clearly viewing conditions under which the tomato would produce the characteristic effect that is associated with black things. The typical response of adherents of relational views of colour to this kind of difficulty is to claim that ordinary colour claims contain an implicit reference to a particular class of perceivers and a particular kind of viewing condition. To say that a tomato is red without qualification is to say that it produces the effect characteristic of red things on *normal* (human) perceivers in *normal* (for humans) viewing conditions. If we fix one term of the relation, then we can talk about colour as if it were an intrinsic property of the object being described.

The main problems that relational views of colour face fall into two categories. As we have seen, the theory attempts to account for ordinary colour talk by making use of the notions of a normal perceiver and normal conditions. There are serious questions, however, about whether a suitable conception of normality actually exists. It is possible to specify precisely the characteristics of a normal perceiver, but then it follows from the substantial variation in human colour vision that there will be extremely few normal perceivers. Thus most people will not be in a position to determine visually the colours of objects. If we offer a more relaxed standard for who counts as a normal perceiver, then there will be variation in the effects of objects within the class of normal perceivers, and the

determinacy in colour attribution that the appeal to normal perceivers was supposed to provide will be lost. Similar problems arise in trying to specify which viewing conditions count as normal. The other main difficulty facing relational theories of colour arises from the necessity of describing the characteristics, the production of which gives an object its colour. In ordinary talk we use words like ‘red’ indiscriminately to describe both the external property and the perceptual experience with which it is associated. Relational theories of colour must find some way of independently characterizing perceptual experiences while avoiding circularity and vacuity.

3 Realist theories of colour

Realist theories of colour hold that colour is a genuine property of physical objects and that objects possess this property independently of their relation to perceiving subjects (see Realism and antirealism §2). Realist theories can be divided into two categories depending on whether or not they take colour to be reducible to physical properties. Physicalist theories of colour hold that colour is a physical property, possibly a complicated one, and that to see the colour of an object is to see that it has a physical property. Physicalist theories of colour bear some analogy to materialist theories of mind and share some of the same advantages and problems (see Materialism in the philosophy of mind). In spite of the resemblance in logical structure between the two types of theory, there is no logical connection between materialist theories of mind and physicalist theories of colour, and it is possible consistently to maintain every combination of affirming and denying the two theories.

The early defenders of physicalist theories of colour were somewhat vague about exactly which physical property they took colour to be identical with and largely confined their attention to defending the possibility that there could be some physical property identical with colour. It is obvious, however, that the relevant physical property must be one that has to do with light, or the reflection of light, since these are the prominent elements in the causal chain leading to the perception of colour. The most suitable candidate, as has been argued by D.R. Hilbert (1987), is the way in which objects reflect light. This property, surface spectral reflectance, is a relatively stable property of the surfaces of objects, which does not vary with changes in the illumination. Unlike its reflectance, the light reaching the eye from an object varies with changes in the illumination in ways that match neither our perceptual judgments of object colour nor our inclination to attribute stable colour properties to objects.

The main problems facing physicalist theories revolve around two connected questions: how is the content of colour experience determined and what is the structure of our colour concepts? Armstrong (1968) clearly saw that any very rich concept of colour is incompatible with physicalism. Most people who use and apply colour concepts are ignorant of the relevant physical and physiological facts. If we build a large amount of colour lore and phenomenology into the concept of colour, then there will be no physical property which will fit the bill. Many of the objections to physicalist theories of colour consist in arguing that some part of our concept of colour is incompatible with the empirical facts. The physicalist’s only response to these arguments is to show that either the empirical facts are misrepresented or the claimed necessary truth about colour is not really necessary at all. Physicalist theories of colour require that colour perception not be transparent, in the sense that any colour perceiver necessarily knows all there is to know about colour. The easiest way to avoid this kind of difficulty is to adopt an externalist theory of content. Externalist theories of content have the effect of breaking any necessary connection between internal perceptual states and what they represent and thereby provide the resources for a defence of physicalism against a class of objections drawn from the assumption of transparency (see Content: wide versus narrow).

Not all colour realists are physicalists, and there have been some philosophers who have claimed that colours are intrinsic properties of physical objects that cannot be identified with any physical property. There are two possibilities available to the defender of such a theory. Either colours are properties over and above all the physical properties and bearing no necessary connection to them, or colours are properties that supervene on physical properties but cannot be reduced to them. These two views bear obvious analogies to dualism and non-reductive materialism in the philosophy of mind. The main difficulty the dualist theory faces is that colours, as perceived, will have no place in the causal chain leading to the perception of colour, which raises serious epistemological problems as to how we could ever know the colour of an object. Taking colour to supervene on the physical properties of objects avoids this difficulty and has the virtue of avoiding many of the other difficulties faced by the theories of colour discussed above. The main difficulties facing the theory of colours as supervenient properties are the general difficulties of understanding the relation of supervenience and what kind of evidence could ever

support a conclusion of this kind.

Combinatory logic

Combinatory logic comprises a battery of formalisms for expressing and studying properties of operations constitutive to contemporary logic and its applications. The sole syntactic category in combinatory logic is that of the applicative term. Closed terms are called 'combinators'; there is no binding of variables. Systems containing the basic combinators S and K exhibit the crucial property of combinatorial completeness: every routine expressible in the system can be captured by a term composed of these two combinators alone. Combinatory logic is a close relative of Church's lambda calculus. M. Schönfinkel first introduced and defined basic combinators in 1920 in assaying foundations for mathematics that avoid bound variables and take operations, rather than sets, as fundamental. H. Curry later rediscovered the combinators (and coined the term 'combinatory logic') independently of Schönfinkel. Curry constructed various formal systems for combinatory logic and, throughout most of the subject's history, was the central figure in the research. In 1969, D. Scott succeeded in constructing set-theoretic, functional models for the lambda calculus and combinatory logic. Since then semantic studies of combinatory systems, together with research on their applications to computer science and further development as foundational systems, have dominated the field.

1 Combinators and the elimination of variables

In his *On the Building Blocks of Mathematical Logic* (1924), M. Schönfinkel sought to surpass Whitehead and Russell's *Principia Mathematica* and Frege's *Grundgesetze* in isolating notions absolutely fundamental to mathematical logic. In addition to employing a Sheffer stroke-like operator for predicate calculus (Sheffer (1913) showed that all truth-functional connectives could be expressed in terms of 'not…and'), Schönfinkel proposed abandoning the type-stratified logical universe of *Principia Mathematica* in favour of one consisting entirely of type-free functions, mathematical operations presupposed by all others, unlimited in their allowed inputs and, hence, self-applicable. Moreover, he looked to reduce the number of all logical symbols (of both first- and higher-order logic) to three: the stroke-like function, a constant function and a 'fusion' function. These were the building blocks from which Schönfinkel intended to analyse logical expressions as compounds of basic operations. In this way, the ultimate operations on which mathematical logic depends - operations usually left implicit and unformalized - were to be revealed to the foundational gaze. As a bonus, this universal analysis was to require a wholesale elimination from logic of the variable.

For a simple example of variable elimination, consider a binary operation $\circ$ which is 'idempotent'; that is, for all x, $x \circ x = x$. To render this relation without bound variable x, one introduces operation symbols or, to use terminology due to H. Curry, 'combinators'. In this case, let O and I be such that $Ox = x \circ x$ and $Ix = x$. Then, to claim idempotency for $\circ$, one writes merely $O = I$. The variable x becomes redundant, for, if we apply both sides of the combinator equation to x, we return the original: $x \circ x = Ox = Ix = x$. Combinators then serve to express general laws, such as those of function application, without bound variables, and knotty issues of substitutability and illicit variable capture are avoided.

In general, a combinator is a variable-free name for an operation (on operations) defined using an equation. A number of combinators are standard and bear conventional names. Some of the most common are S, K, I, B and W, defined as follows: $Sxyz = xz(yz)$, $Kxy = x$, $Ix = x$, $Bxyz = x(yz)$ and $Wxy = xyy$. Schönfinkel, in effect, introduced combinators S and K for the operations he called 'fusion' (*Verschmelzung*) and 'constant' (*Konstanz*). S performs a generalized composition operation and K, when applied to x, yields Kx, the constantly x-valued function of y. I is a universal identity function. B denotes conventional composition of functions, since Bfg, applied to x, gives $f(gx)$. Finally, W realizes diagonalization: Wf, applied to x, yields fxx. If we think of f as a binary function, Wf is the unary function which is f with arguments identified. (Incidentally, here we are exploiting a device known to Schönfinkel, as well as to Frege, but now called 'currying', after Curry. By that device, combinators denote unary operations but achieve the effect of *n*-ary operations ($n > 1$) when iterated.)

2 Combinatory logic

Curry (1900-82), a student of Hilbert who rediscovered the combinators independently of Schönfinkel, devised the first formal systems for (what he termed) 'combinatory logic'. In Curry's systems, the fundamental syntactic

category is that of (combinatory) term, where basic terms are either variables or constants. Compound terms denote applications: if t and u are terms, then so is tu, expressing the application of t to u. Among the constants are the basic combinators K and S. Any term built up entirely from K and S is also called a combinator.

As with the lambda calculus, we can define appropriate notions of reduction, normal form and equality for combinatory terms (see Lambda calculus). The 'reduction' of one combinatory term to another is conceived by analogy with simplifying computation, for example, the reduction of $(3 + 6) \times (10 - 2)$ to 72 by calculation. A 'normal form' is a term which can be simplified no further. Terms t and u are equal whenever they can be linked by a finite sequence of terms $t_0, t_1, \ldots, t_n$ such that, for every k and l, either t_k reduces to t_l or conversely.

Since operations may be viewed both extensionally and non-extensionally, there are extensional ('strong') and non-extensional ('weak') conceptions of reduction and normality, on either of which Kxy reduces to x and $Sxyz$ to $xz(yz)$. Both kinds of reduction are univocal in that, if t reduces to a normal form, it does so uniquely. This is guaranteed by the 'Church-Rosser theorem', which states that, if t reduces to u and to v, then there is a term w to which u and v both reduce. As in the lambda calculus, select combinators can serve as numerals and an arithmetic can be so developed that every partial recursive function is representable within combinatory logic.

It is readily seen that some combinators are definable from others. For example, I is recovered as SKK, since, for any x, $SKKx = Kx(Kx) = x = Ix$. The principle here is general: S and K comprise a 'complete' set of combinators in that every other combinator is derivable from these alone. Indeed, let t be any term, simple or complex, containing only variables from a finite set, say, x, y, z. Then there is a combinator, denoted $[x, y, z]t$, called 'the abstraction of t with respect to x, y and z', containing no free variables and constructed entirely from S and K such that $(([x, y, z]tx)y)z$ reduces (weakly) to t. In effect, Schönfinkel was the first to recognize the completeness of combinatory logic.

The notation '$[x, y, z]t$' is entirely metatheoretic; it denotes a term containing neither free nor bound variables and connotes that the abstraction $[x, y, z]$-operation plays a role in combinatory logic analogous to that played in the lambda calculus by the $\lambda x\, \lambda y\, \lambda z$ abstractor (see Lambda calculus). This loose analogy is made precise by defining functions which inject the set of combinatory terms into those of the lambda calculus so that relevant equality relations coincide. There are metatheoretic functions Λ and C, where Λ maps combinatory terms into lambda terms and C the reverse, so that, for combinatory terms t and u, $C\Lambda(t)$ is the same term as t and, as far as extensional equality is concerned, $t = u$ in combinatory logic if and only if, in the lambda calculus, $\Lambda(t)$ equals $\Lambda(u)$. (The non-extensional versions of the respective calculi are also comparable but the matter is more complex.) The function C employs abstraction in dealing with lambda terms: $C(\lambda x\, \lambda y.t)$, for example, is $[x, y]C(t)$.

Intuitively, a model for (non-extensional) combinatory logic would be a universe D with a binary operation • - representing application - and containing elements k and s which behave, with respect to •, as K and S do. It is easy to verify that such a model satisfies all the equalities of the weak or non-extensional combinatory logic. However, combinatory logic was originally conceived as a doctrine of operations or functions and real difficulties arise in rendering these functions in set-theoretic terms. For one thing, combinatory logic allows self-application: the combinator SS is perfectly well-formed. But no standard set-theoretic function can be a member of its own domain. Moreover, every combinator, unlike every set-theoretic function, admits fixed points. Curry discovered a 'paradoxical' combinator Y, which may be defined $WS(BWB)$, that computes a fixed point for any term: if t is a term, Yt is equal to $t(Yt)$.

In 1969, D. Scott (1976) was the first to overcome these obstacles and give set-theoretic constructions of models (in the above sense) for combinatory logic in which the terms name functions. A key idea was to let combinatory terms name functions which are not arbitrary but continuous. Here, a continuous function on a partial order with limits preserves the order and the limits which exist. Scott's original construction was quite complex; models less complicated to build were soon forthcoming. These semantic breakthroughs inaugurated a period of intense research on combinatory logic and the lambda calculus, stimulating numerous applications of both to computer science.

3 Combinatory logic as a foundation for mathematics

Schönfinkel's original goal, which Curry nurtured and pursued under the rubric 'illative combinatory logic', was

the construction of a comprehensive system for the foundation of mathematics free of types and bound variables, and highlighting those operations essential to logical thought. To be comprehensive, no significant notion was to be banished to the metatheory. Other than the assertion sign, every concept which bears on the system was to be amenable to combination with combinators inside the system.

The strongest of Curry's early illative systems, which appeared in print in 1934, proved excessively comprehensive: Church's students S. Kleene and J. Rosser demonstrated its inconsistency in 1935. Curry himself refined the core of their argument, obtaining the elegant 'Curry's paradox', which shows plainly that even a simple logic of implication cannot be developed in the presence of combinatorial completeness. Curry and his co-workers then sought to avoid paradox by inventing systems to circumscribe, within the class of legal terms, canonical terms standing for propositions. Unfortunately, consistent versions of these systems were too weak to support a comprehensive mathematics. Throughout the middle and late twentieth century, a number of logicians contributed significantly to achieving the goal of Curry and Schönfinkel (a task known as 'Curry's programme' - see Seldin 1980) for illative systems, among them P. Aczel, M. Bunder, S. Feferman, F. Fitch, J. Hindley, D. Scott and J. Seldin. In 1983, M. Bunder published his system HOPC ('Higher-Order Predicate Calculus'), which is an illative system with internal typing and in which a significant portion of Zermelo-Fraenkel set theory can be interpreted.

Comedy

In the narrowest sense, comedy is drama that makes us laugh and has a happy ending. In a wider sense it is also humorous narrative literature with a happy ending. In the widest sense, comedy includes any literary or graphic work, performance or other art intended to amuse us. This entry will leave aside theories of humour and concentrate on comedy as a dramatic and literary form.

Comedy began at about the same time as tragedy, and because they represent alternative attitudes toward basic issues in life, it is useful to consider them together. Unfortunately, several traditional prejudices discriminate against comedy and in favour of tragedy. There are four standard charges against comedy: it emphasizes the animal aspects of human life, encourages disrespect for leaders and institutions, is based on malice, and endangers our morality. These charges are easily answered, for none picks out something that is both essential to comedy and inherently vicious. In fact, once we get past traditional prejudices, several of the differences between comedy and tragedy can be seen as advantages. While tragedy tends to be idealistic and elitist, for example, comedy tends to be pragmatic and egalitarian. While tragedy values honour, even above life itself, comedy puts little stock in honour and instead emphasizes survival. Tragic heroes preserve their dignity but die in the process; comic characters lose their dignity but live to tell the tale. Most generally, comedy celebrates mental flexibility and a realistic acceptance of the limitations of human life. The comic vision of life, in short, embodies a good deal of wisdom.

1 The demeaning of comedy

Although comedy and tragedy grew up together, and many dramatists from Sophocles to Shakespeare wrote both, tragedy is usually thought superior to comedy, and is often judged the only important dramatic form. Tragedy is called ‘serious’ drama, comedy ‘light’ drama. The low status traditionally held by comedy is revealed by two meanings that arose for the word ‘comical’: ‘befitting comedy; trivial, mean, low; the opposite of tragical, elevated, dignified’ and ‘of persons: low, mean, base, ignoble or clownish’.

The demeaning of comedy, and of humour generally, began with Plato. Four main charges are traditionally offered. One is that comedy, which had its origins in animal masquerades, phallic processions and similar revelry, emphasizes the animal side of human nature. Plato found the Old Comedy of his time still wild and vulgar. In his mind the licence of comedy encouraged the undermining of our rationality by our lower physical nature. When laying down rules for the education of the young guardians in his ideal state, Plato insisted that they must not be prone to laughter and that the literature they read should not show the heroes and gods laughing too heartily.

Comedy is also charged with encouraging irreverence toward leaders and institutions. A society, like an individual, needs rational control, and that requires respect for leaders and traditions. But comedy can make fun of anything; Greek comedy even lampooned the gods. Plato was probably especially resentful of the ridicule his teacher Socrates suffered in the comedy of Aristophanes.

Throughout history, opposition to comedy and laughter has been strongest in societies which emphasize physical restraint, decorum and conformity. Many medieval monastic orders had statutes forbidding laughter. The Puritan and Victorian eras saw many condemnations of comedy and laughter. The more authoritarian the regime, the greater its suppression of comedy. Hitler even set up ‘joke courts’ to punish those who made fun of his regime - one Berlin cabaret comic was executed for naming his horse Adolf.

The third charge against comedy, and humour generally, is that laughter is inherently mean-spirited. According to Plato, the object of laughter is vice, and specifically people’s ignorance about themselves. Dramatic characters and real people are comic to the extent that they think of themselves as wealthier, better-looking, more virtuous or wiser than they really are. Our laughter at their self-ignorance involves a kind of malice towards them - a ‘pain in the soul’, as Plato called it - that is not only antisocial but harmful to our own character.

Aristotle agreed with Plato that the essence of laughter is ridicule. Most people carry humour too far, he claimed, not worrying about hurting the feelings of those at whom they laugh. This view of laughter was later called the superiority theory. Its most famous proponent was the seventeenth-century philosopher Thomas Hobbes, who said that the cause of laughter is the sudden glory we feel when we judge ourselves to be doing better than someone

else. Those who laugh the most, according to Hobbes, are those who are conscious of the fewest abilities in themselves. They have to search out the imperfections of others in order to feel good about themselves.

The last charge against comedy is that it is full of gluttons, drunkards, liars, adulterers and other base characters, who are bound to have a bad influence on our own morality. Aristotle said that comic characters are worse than real people and warned that children should not be allowed to attend comedies because they would be led to imitate the vices they saw on the stage. The purported danger of comedy to morality has been cited many times. It was part of the English Puritans' rationale for outlawing drama. Rousseau used it against the comedies ofMolière. The weight attached to it can be judged from the number of writers and critics who felt obliged to argue that in laughing at immoral behaviour, we reject it, so that comedy discourages rather than encourages vice.Ben Jonson, Sir Philip Sidney, John Dryden, Henry Fielding, George Meredith, Henri Bergson and dozens of others defended comedy by citing its moral utility in this way.

2 Answering the charges

While the four charges against comedy apply to some plays and comic works, none applies to all of them, and none makes a convincing case that some characteristic is both essentially vicious and essential to comedy.

Comedy's emphasis on the animal side of human nature may be a fault if we share Plato's low opinion of the body and of the physical side of life. Similarly, the irreverence of comedy may be objectionable if we agree that our leaders and institutions deserve reverence and not critical questioning. But we need not share Plato's views on these issues. Indeed, a good case can be made for saying that comedy is valuable precisely because it reminds us of our physicality and because it keeps us thinking critically about our leaders and institutions.

The other two charges against comedy - that laughter is an expression of feelings of superiority and malice, and that the base behaviour of comic characters might rub off on us - do focus on two things that are reasonably considered objectionable. But they fail to show a necessary connection between either of these and comedy.

Although the first of these charges has a long history, it has seldom been carefully examined. If the superiority theory is right, then our laughter is always directed at a person, and in laughing we must be comparing ourselves favourably with that person. But, as Francis Hutcheson showed a century after Hobbes, neither of these consequences is true. We sometimes laugh when no one else is involved, and we sometimes laugh when someone seems superior to us. If I open my front door on a November morning to find a foot of snow where there was grass the night before, I may laugh - not at anyone, not even at the snow (in the sense of ridicule), but simply out of surprise. Similarly, I may laugh at clever rhymes or other wordplay in a comedy without comparing myself to the character speaking the lines or to anyone else. Some action which is better than we expected may also make us laugh in surprise. A stock character in early film comedy, for example, is the plucky hero, such as Charlie Chaplin or Buster Keaton, who gets out of trouble with an ingenious acrobatic stunt that we would never have thought of, much less been able to execute. The stunt makes us laugh, though the character looks superior to us.

The last charge against comedy - that we are likely to imitate its base characters - has probably been made more often than any other. But seldom has any evidence been given for it. Do people who see a lot of comedies have a higher rate of drunkenness or adultery? Are people who laugh at hypocrisy more likely to become hypocrites themselves? These are empirical questions calling for empirical research. Several characters, such as the boor, the windbag and the pompous ass, seem to be comic only if we think that their traits are undesirable - someone who emulated them would not find them funny. It may be that other comic characters, such as the smooth-talking liar, do elicit emulation from some people. But that has never been established, nor has it been shown that these characters outnumber the ones who discourage emulation. In short, like the other charges against it, the claim that comedy threatens our morality is largely an ancient prejudice.

3 Comedy and tragedy

Once we set aside traditional prejudices against comedy, we can compare it more equitably with tragedy. The most general similarity between the two is their focus on the incongruities in human life - the ways in which our experiences do not match our expectations. As William Hazlitt said, humans are the only animals who laugh and weep because they are the only ones who are struck by the difference between what things are and what they ought to be.

It is in their responses to life's incongruities that comedy and tragedy differ. Both see misfortune, vice, folly, and, in general, the gap between the real and the ideal as part of the human condition. But tragedy sees these leading to downfall and death, while comedy sees them as something we can live with and even enjoy.

Comedy and tragedy also have different attitudes towards the physical side of human nature. Comedy accepts the limitations of our bodily existence and celebrates acts like eating and sex. Tragedy bemoans our physical limitations and often identifies the human being with the mind, spirit or soul. In general, comedy is more physical and active, and tragedy more intellectual and contemplative. Falstaff might deliver a monologue while gnawing on a leg of mutton: it is inconceivable that Hamlet would do so.

The idealism and dualism of tragedy carry over to its vision of society. In tragedy only a few people are important and only their lives are of interest. The main characters in tragedy, as in the epic, are heroes, typically male rulers or warriors. In comedy, by contrast, there is a greater variety of characters, women are more prominent, and central characters may come from any social class. While the language of tragedy is elevated, the language of comedy is common speech.

Tragedy usually focuses on the suffering of one elite character in an extraordinary situation; comedy involves several characters from different social classes in ordinary situations. When comedy has a central character, that person, unlike the tragic hero, is not exalted above other human beings. Tragedy emphasizes the dignity and pride of the hero, which are often based on the code of honour of a male-dominated, power-based, militarist ideology. Indeed, it is often just this ideology which gets the hero into the tragic situation. Comic characters, not bound by codes of honour, may lack dignity, but at the end of the comedy they are still alive. Indeed, they are often found attending a wedding or another life-affirming celebration.

Furthermore, because comedy values life - especially the life of the community - over honour, it emphasizes the social support we all need. In tragedy, by contrast, the hero is more of a 'loner'. Many comic plots are based on reconciliation and peacemaking, while no tragic plots are. As Aristotle noted, in comedy enemies sometimes become friends, but in tragedy they never do.

4 Comic wisdom

The popularity and value of comedy lie largely in its vision of human life, which contrasts sharply with the dominant ideologies of Western culture. Those ideologies treat as virtues such traits as respect for authority, duty, honour, single-mindedness, courage and a capacity for hard work. These have been promoted by armies and other patriarchal institutions since ancient times. An important way of inculcating them in society at large has been to celebrate them in epic and tragic art, which are full of military imagery. Indeed, patriarchies try to get us to think of everything in military terms. In the USA, social programmes are called 'the war on poverty'; medical research is called 'the war on breast cancer'; even programmes to stop violence are 'the war on violence'! When military metaphors sink deep enough into our culture, life itself becomes a series of battles.

While blind obedience, single-mindedness, the ability to work constantly, and the willingness to die or kill on command are important for the conduct of war, it is not at all clear that they are virtues in all areas of life. Thus alongside the official ideology promulgated by epics and tragedy there has always existed an alternative ideology of comedy. Instead of promoting military virtues, comedy promotes the questioning of authority, mental flexibility, playfulness and the value of life. All of these threaten institutions of power in various ways, and as a result comedy has been suppressed in most cultures. However, because it addresses deep human needs, it has survived.

Comedies have different kinds of characters. Many serve as negative role models, examples of how not to act. In laughing at the miser, the prude and the pedant, as Henri Bergson pointed out, we are recognizing their mechanicalness, their ineptness at living a human life. But most comedies also have at least one character that we identify with and may even admire. Many of the roles played by Charlie Chaplin, Mae West and Groucho Marx are of this type. These characters are so different from epic and tragic heroes that their usual name, 'comic heroes', is misleading. We can call them comic protagonists.

The attitudes of these characters embody what is most valuable in comedy. Unlike tragic heroes, they play as well as work. They are not unwaveringly committed to any cause; nor are they prepared to die, or kill, to achieve their

goals. Like tragic heroes, they face problems and enemies, but instead of confronting them head on with violence, they use trickery, perhaps by turning the power of the threat against itself, or with reverse psychology. When all else fails, they are not ashamed to run away. As the old saying goes, you're a coward for only a moment, but you're dead for the rest of your life.

Comic protagonists differ most notably from tragic heroes in their mental flexibility, a trait which comedy celebrates. The characters who lose in comedy are rigid creatures of habit; those who succeed are adaptable and think on their feet. Unlike tragic heroes, comic protagonists do not have fixed categories for thinking or acting. They can view situations from several perspectives and see many possibilities. Much of their thinking is lateral rather than vertical, to use Edward de Bono's terms.

When confronted by problems, tragic heroes are given to emotions that make them mentally rigid and even obsessive. Comic protagonists keep an unemotional clearheadedness in the face of misfortune that allows them to think rather than feel their way through challenges. They do not engage in self-pity or curse their fate, but are more likely to laugh at their problems, as tragic heroes never do. As a result, they are more likely to bounce back from their mistakes and learn from them. The contrast here is fittingly generalized by Walpole's maxim, 'This world is a comedy to those that think, a tragedy to those that feel'.

Since emotional disengagement and the ability to imagine alternatives are a big part of human freedom, comic protagonists are considerably freer than tragic heroes. They are often in charge of their lives as tragic heroes are not, and they end up victors, while tragic heroes end up victims.

It is often said that the tragic vision of life embodies wisdom. Solemnity and pessimism are considered hallmarks of wisdom. Western thinkers, with a few exceptions such as Democritus and Nietzsche, have usually thought wisdom to be a kind of seriousness about life. But that is all part of the traditional prejudice against comedy. Judged fairly, the comic vision reveals at least as much wisdom as the tragic.

Indeed, if wisdom includes emotional disengagement, seeing life from a higher perspective than usual and seeing it objectively rather than from a self-privileging position, then comedy seems wiser than tragedy. If wisdom includes a realistic attitude towards life, comedy's tolerance for human limitations and its emphasis on adapting ourselves to an imperfect world seem to make it more realistic than tragedy. More fully than tragedy, too, comedy represents the richness of life - especially social life - in the many ways it may be lived and appreciated.

Comic characters make mistakes and suffer misfortunes, but through it all they are at home in their world, and they get by with a little help from their friends. Tragic characters, with their elitism and idealism, are not satisfied with living a merely human life. The central lesson of comedy is that we are finite and prone to error, but with a sense of humour we can still be happy.

The capacity for happiness seems to need some psychological technique for coping with finitude and fallibility, and humour is easily the most effective. Psychological studies have shown that humour is correlated not only with self-esteem but with creativity and a tolerance for ambiguity, diversity and change. Furthermore, humour has medical benefits - it blocks negative emotions, counteracts stress, boosts the activity of the immune system, reduces pain, and even has a laxative effect!

Both comedy and tragedy are reactions to the human condition, but as a dramatic form, an artistic sensibility, and an attitude toward life itself, comedy seems truer to human nature. The displacement of tragedy by comedy and tragicomedy in the twentieth century seems a step towards the acknowledgement of this fact.

Comenius, John Amos (1592-1670)

Comenius (Jan Amos Komensky), a Czech philosopher and theologian, was one of the founders of modern educational theory. As a Protestant minister he had to leave Bohemia during the Counter-Reformation, spending most of his life in various European countries. His greatest work (not published during his lifetime) is De rerum humanarum emendatione consultatio catholica (A General Consultation on the Reform of Human Affairs), whose leading idea is the demand for a harmonious arrangement of human relations on the basis of rational enlightenment, the development of education, and the instruction of all humankind. Comenius builds his philosophy on an idea of human nature understood as grounded in an active creative force perpetually leading to improvement: instruction and education are the tools to fulfil this humanitarian ideal. To lend force to this, Comenius constructs a whole ontological system, in which a harmonious development of the whole of existence leads to human reality as its highest tier.

Comenius was born in southern Moravia; his family belonged to the Czech reformist church known as the Unity of Brethren. After studies at the Union's schools in his own country and at the Universities of Herborn and Heidelberg, Comenius became a preacher of the reformed church, and later its bishop. His activities in his homeland - where he had started working on a great encyclopedia of universal knowledge in the Czech language and on his first educational works - were interrupted by the anti-Habsburg uprising of the Bohemian Estates (1618-20) which ended in the loss of the kingdom's independence. Enforced re-Catholicization and persecution of other religions followed. For a few years Comenius went into hiding while writing his best-known Czech book, the symbolic prose *Labyrint světa a ráj srdce (The Labyrinth of the World and the Paradise of the Heart)*, but in 1628 he left his country for good and settled in Leszno (Lissa) in Poland. Here he created his important educational works, *Didactica* and *Janua linguarum reserata*, where he demands equal rights to education for all people, and also his first pansophic works, *Pansophiae prodromus* and *Conatuum pansophicarum dilucidatio*, where he makes proposals for reforming political relations in the world ravaged by the Thirty Years' War.

Comenius' educational and pansophic work found much support in Europe, and the English Parliament invited him to come to London to reform the education system and pursue his general efforts at universal improvement there. He recruited influential patrons such as James Ussher, John Selden, John Pym, Samuel Hartlib and others. Impulses from Comenius' stay in England contributed to the appearance of his *Via lucis* which contains - in addition to a proposal for an international organization of scientific work - Comenius' historical philosophy: Darkness (feudalism, the rule of the papacy and the Habsburgs, and general backwardness) will be driven away by Light because history is a tiered process where the amount of Light grows continuously out of the struggle with Darkness, in the form of rays of general education and rational enlightenment. Comenius expected that the period of the voyages of discovery, expansion of trade, book printing, science and technology will soon usher in an era of enlightenment, peace, international co-operation and prosperity. This should be helped by the spread of education into all layers of society, and to each individual.

The outbreak of the Civil War curtailed Comenius' activities in England. He left for Sweden to reform its educational system, hoping at the same time that Sweden's policy and participation in the Thirty Years' War might result in the liberation of the Kingdom of Bohemia from the rule of the Habsburgs and facilitate the repatriation of its political emigrants, a hope soon to be proved forlorn. During his stay he continued to expand his pansophic plans but found the Swedes uninterested. The years 1651-4 were spent in Hungary reforming its educational system, and Comenius then returned to Leszno where a fire in the town destroyed his library and all his manuscripts. Due to the change of political climate in Poland he could not stay there much longer, and in 1656 he left for Amsterdam where he spent the remainder of his life.

In the Netherlands Comenius published (with the help of the City of Amsterdam) his educational work *Opera didactica omnia* (1657-8). At the same time he pressed on with *De rerum humanarum emendatione consultatio catholica (A General Consultation on the Reform of Human Affairs)*, a six-volume work which represents a synthesis of his life efforts. He almost succeeded in finishing it: some parts were published, but he found no support for a complete edition. Nor could his heirs arrange publication, for the same reason. For a long time the manuscript was believed lost. Only in 1935 was it discovered in the library of the Pietistic Orphanage in Halle, and

the first complete version was published in Prague in 1966.

The *Consultation*, in addition to its prologue ‘To the Lights of Europe’ which addresses Europe’s educated elite, consists of seven parts: ‘Panegersia’ (Universal Awakening) defines human matters, analyses their disconsolate state and calls for a quest for improvement; ‘Panaugia’ (Universal Enlightenment) explores possible ways to reform, and selects the most effective of them, ‘the bright light of Minds spreading everywhere and to everything’; ‘Pantaxia’ (Universal Order) or ‘Pansophia’ (Universal Science), the fundamental section of this work, outlines Comenius’ ontology by describing different tiers of world affairs right to the top one - an ideal human society; ‘Pampaedia’ (Universal Education) proclaims education for all, including adults, throughout their lives, including even ‘entirely barbaric nations’ which should be freed from ‘the darkness of their ignorance’; ‘Panglottia’ (Universal Eloquence), a general study of languages as a means for spreading the light, including an artificial philosophical language; ‘Panorthosia’ (Universal Improvement) shows how - thanks to all so far discussed - the state of education, religion and public administration can be improved ‘so that by God’s command an Enlightened Pious and Peaceful Age can be brought to Earth’; ‘Pannuthesia’ (Universal Call), a challenge to all educated people, lords spiritual and temporal, ‘as well as all Christians without difference, consciously to press for the bringing about of these desired and desirable things’.

Comenius’ thought is characterized by his effort to achieve synthesis. He accepts all sorts of intellectual ideas from the present and past, transforms them and incorporates them into his conceptual structures. First and foremost he brings to fruition the Czech Reformation tradition, the roots of which go back to Jan Hus. From this tradition stems his emphasis on the activity of humans - free beings who, in striving for perfection, come close to God, and transform the world through their action. In this he does not consider humans to be just a ‘res cogitans’ (a thinking substance), and does not reduce them to mere intellectual subjectivity. He sees humans in their complexity, with a developed emotional component and above all with a will which dominates other forces and attributes of human existence. Such a being has all the prerequisites for working upwards again to human perfection, once lost by succumbing to evil and vice.

Comenius built his early philosophy on the empiricism of Bacon. But this did not entirely satisfy him, and he searched for a universal knowledge which would be not just an agglomeration of empirical data but a logically structured whole where empirical findings would exactly fit into a solid framework of fundamental principles, to be found with the help of metaphysics. Comenius’ image of the world was initiated by Neoplatonism and by Nicholas of Cusa but these impulses are again re-shaped. He combines the dynamic descendancy of Neoplatonic Nature with the non-dynamic ascendancy of Aristotelian-Scholastic Nature, creating the picture of a dynamic ascendant world where practical human activity plays an active part. It is not a purely linear process as it has its regresses, but as a basic direction it points to the highest step - an ideal, harmonious human society. Comenius’ lifelong efforts for a universal reform aim at this ideal, as illustrated by his final project outlined in *Consultation*.

Common law

Common law and custom are features of most enduring legal orders. In English law the concepts have taken on special and interrelated significance, since English law is said to be grounded in common law and that in turn is said to derive from custom. According to classical common law theory, which crystallized in the seventeenth century, common law grew from the customs of the English people. It was not made by legal officials, as statutes are. Change was accommodated in this theory, on the basis not of identity *of elements of law over time but of* continuity*, a continuity of authority and reception of legal customs, and of the traditional legal order which declared them to be law. The role of legal officials - particularly judges - was to interpret and declare legal custom; their judgments provided* evidence *of it. They did not make it or invent it. This mode of development through continual interpretation and reinterpretation of the significance and bearing of the legal inheritance was, according to common lawyers, better adapted to social complexity, change and variety, and also to human epistemological and practical limitations, than attempts to cover any field with legislation.*

This theory was largely eclipsed in nineteenth-century England by the theory of legal positivism, and with it were eclipsed for a time some useful insights into social complexity and institutional limitations. Also lost was a sense of the complex dialectic between continuity and change in legal and institutionalized traditions. In its best moments, common law theory had such a sense.

1 Common law as custom

Common law is a term employed in many legal systems to mark a contrast between law which is in some way general or ‘common’ in scope - though the ways considered relevant differ markedly between different legal orders - and more particular types or branches of law once or concurrently applied in the same legal order. Custom, too, has figured widely as a significant term of art within complex legal orders (Kelley 1990). It typically refers to an element or source of law - unwritten, traditional, old, local - to be distinguished from other, usually newer, more deliberate, more explicit, written sources, which apply on a territorial rather than a communal or ‘personal’ basis, and which are administered by officials (Constable 1994). Both common law and custom are then, in part, contrast terms by reference to other aspects of legal systems; and frequently the contrast in mind is between the two of them.

Today when the common law is mentioned, however, it is usually in connection with the English legal tradition, and that tradition is distinctive in the way in which it has purported to connect, rather than contrast, common law and custom. For while it is acknowledged in this tradition that the institutions that administered common law supplanted those of customary law to form a national law, common lawyers have long insisted that the substance of English common law is drawn, and derives its legitimacy from, custom.

After the eleventh-century Norman conquest of England, the King’s Courts gradually extended their sway throughout the kingdom. Institutionally this was at the expense of a variety of local assemblies, tribunals, customary bodies and practices. Substantively, too, the centralized application of written laws had profound transformative effects on oral customs and traditions, even when the courts claimed to be applying customary law (Constable 1994). The law dispensed by the King’s Courts came to be known as the common law. This has led to one broad and two somewhat narrower uses of the term.

In its now most familiar usage, ‘common law’ is a global term for the legal tradition that was developed in Britain by these courts over centuries, and spread to its legal offshoots, such as the USA, Canada, Australia and New Zealand. The common law, in this sense, is most often contrasted with the civilian tradition (see Roman law §3) of continental Europe (and erstwhile colonies of European countries).

In a second and narrower usage, internal to the common law tradition, the law dispensed by the common law courts was distinguished from the specific ‘equitable’ interventions by the Lord Chancellor and the Court of Chancery to supplement traditional common law remedies (see Justice, equity and law §4).

Third, when statutes enacted by Parliament became prominent sources of English law, they were also distinguished from the common law developed by the courts. This third distinction persists, though statutes are more and more general in scope and effect and in many areas have come to override the common law.

English common law practice had many features that distinguished it from other legal traditions. The common law also spawned a distinctive theory of law. Classical common law theory crystallized most clearly in the seventeenth century and maintained its influence through the eighteenth. It insisted - to the dismay of Hobbes, Bentham and other legal positivists - that the common law, far from being made by any identifiable institutions or persons - kings or parliaments or even judges - grew from the customs of the English people. As Sir William Blackstone put it in the eighteenth century, the common law was an 'antient collection of unwritten maxims and customs' (Blackstone [1765-9] 1979, vol. 1: 17), and '[t]he only method of proving, that this or that maxim is a rule of the common law, is by shewing that it hath been always the custom to observe it' (Blackstone [1765-9] 1979, vol. 1: 68). Although the decisions of judges were acknowledged to be crucial elements in the development of the tradition in this perception, they did not make the common law, but were merely evidence of it.

The claim that the common law is grounded in custom addresses, often without much differentiation, descriptive, explanatory and normative issues, as well as social theory and legal and political philosophy. Several matters need to be unravelled, central among them the following three. First, whether, and if so how, an account of law as custom can make sense of legal change. Second, if law is popular custom, what is the role of legal officials? Third, what are the normative implications of the customary character attributed to the common law; what, if any, are its particular virtues?

2 Change and continuity in the common law

One of the most important interpreters of the language of the common law, Pocock (1987), has argued that the common lawyers' identification of common law and custom involved them in a paradox, stemming from an ambiguity inherent in the concept of custom itself. On the one hand, '[i]f the idea that law is custom implies anything, it is that law is in constant change and adaptation, altered to meet each new experience in the life of the people' (Pocock 1987: 36). On the other hand, 'it is equally possible to regard [custom] as that which has been retained throughout the centuries and derives its authority from its having survived unchanged all changes of circumstances' (Pocock 1987: 37). Pocock took the views of Sir Edward Coke, the seventeenth-century common lawyer and (from 1606-16) Chief Justice, as emblematic of the tradition, and emphasized that Coke and his contemporaries seemed largely in thrall to the second, unhistorical, interpretation. Later scholarship (Burgess 1992), and some clarifications by Pocock himself, suggest than even Coke might have been less single-mindedly ahistorical than Pocock was taken originally to suggest and, more important, that Coke's was never the interpretation widespread among the most distinguished and sophisticated common lawyers.

Such lawyers, among them in the seventeenth century Spelman, Vaughan, Selden and Hale, in the eighteenth Blackstone and Lord Mansfield, had no time for immemorial origins. Since evidence was poor and incomplete, there was no way of knowing such origins with any exactness. In any event it is not in the nature of law to remain unchanged:

> From the Nature of Laws themselves in general, which being to be accommodated to the Conditions, Exigencies and Conveniencies of the People, for or by whom they are appointed, as those Exigencies and Conveniencies do insensibly grow upon the People, so many times there grows insensibly a Variation of Laws, especially in a long tract of Time.
>
> (Hale [1713] 1971: 39)

Indeed, while Hale believed that deliberate legal change should be approached with caution and humility, he also thought it absurd to imagine that the law should remain unchanged: 'The matter changeth the custom; the contracts the commerce; the dispositions, educations and tempers of men and societies change in a long tract of time; and so must their lawes in some measure be changed, or they will not be usefull for their state and condition' (Hale [1665] 1787: 269-70).

If there was all the adding, subtracting, altering and creating that Hale describes, what held things together, in the absence of the glue of identity; what made all these different laws part of the same 'common law'? For Hale, and the common law tradition more broadly, change was an intrinsic characteristic of a law in constant organic evolution. Like a person, the law maintained its continuity through a process of continual change and growth. Or, to change the metaphor as several of them did, the common law survived change just as 'the Argonauts Ship was the same when it returned home, as it was when it went out, tho' in the long Voyage it had successive

Amendments, and scarce came back with any of its former Materials' (Hale [1713] 1971: 40). What made all its elements part of the same law was not their changelessness but their continuity. And this continuity had more to do with the continuing authority and reception of the law than it did with any demonstrable objective longevity of all its elements.

The source and ground of this continuity was twofold. First, it stemmed from the anchoring of the common law, developed by the courts, in popular customs which had been 'handed down by tradition, use and experience' (Blackstone [1765-9] 1979, vol. 1: 17) and had survived by constant transmission, reception, interpretation, refinement, transformation and application, from 'time whereof the memory of man runneth not to the contrary' (Blackstone [1765-9] 1979, vol. 1: 67). These customs had developed over the life of the country, and had indeed become constitutive of 'the people, into whom their ancient laws and customes are twisted and woven as a part of their nature…' (Hale [1665] 1787: 255). As these customs displayed continuity through change, so too did the common law, whose officials continuously drew upon them, interpreted them, rendered them explicit and made them binding.

Second, continuity was embedded in the characteristic practices of the legal institutions themselves, for these practices - and particularly those of the common law courts - were best understood as customary ones. As A.W.B. Simpson has revived and endorsed this aspect of the common law account:

> the common law system is properly located as a customary system of law in this sense, that it consists of a body of practices observed and ideas received by a caste of lawyers…. The ideas and practices which comprise the common law are customary in that their status is thought to be dependent upon conformity with the past, and they are traditional in the sense that they are transmitted through time as a received body of knowledge and learning.
>
> (Simpson 1987: 376)

Given such continuity, it was possible to accept, even to advocate, reform of the law, so long as it was done by common law methods, materials and institutions. And much of the most distinguished common law thought of the eighteenth century was devoted to advocating legal reform of precisely that sort (Lieberman 1989).

3 Judges and the common law

Notwithstanding their insistence that the common law reflects and rests upon the customs of the English people, not every custom was law. Customs became recognizably legal in the common law when legal officials recognized them (though this was not, for common lawyers, the source of their authority). Coke, Hale and Blackstone all paid great attention to the activities of such officials. However, whereas legal positivists insisted upon the primacy of legislators, the common law tradition did not. Instead its focus was on the common law judge. The declaration, determination, refinement, alteration and transformation characteristic of common law development were primarily the work of the judges of the common law courts: 'the depositary of the laws; the living oracles, who must decide in all cases of doubt, and who are bound by an oath to decide according to the law of the land' (Blackstone [1765-9] 1979, vol. 1: 69).

Given the acknowledged centrality of judicial pronouncements in its development, it is not surprising that, increasingly from the eighteenth century, the common law has been referred to as 'judge-made' law, distinguished in this character from statutes, which are made by parliaments. To put things this way, however, is implicitly (and today typically unconsciously) to reject the common law understanding of law altogether, in favour of understandings from within the tradition of legal positivism, which - in legal philosophy - has largely overwhelmed that of the common law. For the common lawyers did not view the judge as lawmaker, but as interpreter and declarer of custom, directly or as filtered through earlier judicial decisions; in Coke's words, 'the mouth of the law (for *judex est lex loquens* [the judge is the law speaking])'. This is not a passive role, but nor is it a legislative one. And while common law theory may not furnish an adequate account as it stands, it is neither unperceptive nor absurd.

The positivist critics of common law theory conceived of law as a system of substantive rules, made deliberately by particular persons or institutions (see Legal positivism). Existing rules would either cover a particular case, or not. If the former, the judge's obligation was to apply the rule to the case. If the latter, the judge would have to

supplement the rule in a legislative or quasi-legislative manner. To common lawyers, this set of alternatives would seem unrealistic and impoverished.

On the one hand, well into the nineteenth century common law *practitioners* tended not to think of the law as a collection of substantive rules at all. Rather it was a system of reasoning, and a collection of procedures and remedies, to be adapted to cases as they came before the court. Substance, on this view, came 'from below, in a constant feeding from society' (Lobban 1991: 79).

On the other hand, common law *theorists* did believe that there were substantive rules of the common law, but did not regard them as simply to be applied or made. In any event, unlike statutes, they did not come in a fixed and delimited textual form, ready to be applied. The meaning and bearing of customs and precedents was rather of continual argument, interpretation and reinterpretation. More generally, common law theorists regarded the law, not as a systematic collection of discrete rules, but as a traditional or customary order, of language, thought, maxims, principles, understandings, values and rules - with its own ways of knowing, thinking and arguing, handed down over generations. Lawyers and judges are trained and participate in this order, and interpret it. The judges are the authoritative guardians of this tradition. They conserve it, bring it to bear on particular cases, adapt, apply and transmit it. New things are said and done, of course, on this 'Argonauts Ship' - but by experts working from inside, not out, with materials already on board, and with a keen and experienced sense of the risks involved in straying too far.

The notion here is one of skilled and experienced participants in a familiar and intricate customary order, who deal with both repeated and new problems and changing circumstances by working with old materials. Moreover they do not merely work with those materials, but think in terms that they provide, making distinctions and analogies that make sense in their terms, terms endogenous to the legal materials rather than imposed on them from without. Here, to vary the metaphor yet again, not merely is the statue within the block of stone, but so too are the tools and even the sculptor as well.

Morever, the common law judges are not merely participants in the legal tradition; they are *experts* in the law. This is an expertise not available to everyone without long experience and training. Rather, as Hale observed, 'men are not borne Comon Lawyers' (Hale 1966: 505). Without training and long experience they lack what Coke called 'the artificial reason and judgment of law, which law is an act which requires long study and experience, before that a man can attain to the cognizance of it' (Coke [1608] 1907: 1342-3).

4 The virtues of the common law

An intensely live question, perhaps even now, was what, if anything, England gained from law which was predominantly of this sort: grounded in custom, and determined by judges. More generally, what might any legal order have to gain from law which, unlike legislation 'is not laid down; customs, we know, grow up' (Simpson 1987: 363)? Simply put, the answer of Jeremy Bentham and his followers to these questions was: nothing much and nothing good. For the early positivists' model for law was overwhelmingly legislative. Legislation was the model both for what law is and for what good it can do. Laws are the general commands of legally unlimited sovereigns to habitually obedient subjects. They can do good if clear-headed, deliberate, purposeful legislators issue explicit and unambiguous general commands to deal with social problems and to reform the law - particularly the common law. On this view, either the 'common law' really is inchoate custom or judicial resolution of particular disputes - and then it is no law at all, for no general commands have been issued - or it is purported general commands wrested from individual cases, but in that case power has been arrogated by the 'sinister interests' of 'judge and co.', as Bentham described the masters of the common law.

The common lawyers, by contrast, believed that the common law owed its moral authority (which they did not always sharply distinguish from its legal validity) to its immemorial reception, rather than to its legally irresistible imposition. And they praised it above all for those features which most distinguished it from legislation. Many of the themes of common law theory were elaborated more famously by Edmund Burke (§3) and more recently by F.A. Hayek. They are elements of what might be called the methodological conservatism of common law theory.

First, there is a stress on the irreducible complexity and interconnectedness of social life. The problems and circumstances of life are extraordinarily various, complex, interdependent and changing. Many of the most successful institutions have been the products of no one's design, and the reasons for their success might be

unknown to anyone in particular. There is too much to know for any individual adequately to understand what makes for success in legal arrangements or social arrangements generally - even those that already exist - let alone confidently to predict the results of legal interventions (see Social theory and law §5).

Given the inherent complexity of the world, then, and the inescapable limitations on what we can know and what we can hope to do, thoughtful, cautious, corrigible elaboration and refinement of solutions is preferable to imperious imposition of them. The incremental methods of the common law are suited to the first; legislation to the second. For unlike legislators, as the eighteenth-century Scottish jurist Lord Kames (see Home, H. (Lord Kames)) insisted, '[a] court of justice determines nothing in general; their decisions are adapted to particular circumstances…. They creep along with wary steps, until at last, by induction of many cases…a general rule is with safety formed' (quoted in Lieberman 1989: 162).

Moreover, common law judges do not creep unguided, with just their puny individual 'natural' reason to light their way. For the common law in which they are immersed provides them with a great deal on which to draw. Given the difficulties in doing so, customs that have survived some long time must, at the very least, be presumed to have weathered and adapted to many trials, both literal and metaphorical. Common law judges have the vast storehouse of cases and decisions to draw upon. This law, in its organic and recorded development, encompasses multitudes of cumulative decisions, and these draw upon social customs since time immemorial. These customs - and the judicial reflection upon and refinement of them - embody, or at the very least should be presumed to embody, wisdom far deeper than could be available to any unaided individual, for 'time is the wisest thing under heaven' (Hale [1665] 1787: 270) and the common law is 'fraught with the accumulated wisdom of ages' (Blackstone [1765-9] 1979, vol. 4: 435).

Some interpreters have suggested that the common lawyers favoured custom over reason, but that is not the way they saw it or put it. On the contrary, they insisted that the common law combined both; indeed that its attention to the former uniquely revealed the dictates of the latter. At its most philosophical, this is a variation on Aquinas' distinction (see Aquinas, T. §13) between *deduction* as one way in which particular conclusions can be derived from the natural law, and *determination*, 'of certain general features… like that of the arts in which some common form is determined to a particular instance…. So the natural law establishes that whoever transgresses shall be punished. But that a man should be punished by a specific penalty is a particular determination of the natural law' (*Summa theologiae*, IaIIae.95.2). Determinations will vary according to the ways in which circumstances, customs, other particular conditions and human ingenuity themselves vary. Determinations cannot conflict with the natural law from which they are derived, but nor are they uniquely correct implications of them. For there are no such uniquely correct implications. The common law, dealing with the complex particularities of social life, had general elements of the first sort, but in its detail was mainly of the second. Indeed it is a remarkable store of such determinations, as adapted to and coloured by the particular, complex and variable conditions in which the law must operate, and refined by the sustained application of the 'artificial reason and judgment of law'.

In this way one could insist on the existence of a law of nature, accessible to reason, which the common law could not violate, and at the same time insist that laws apt for some people at some times could not simply be transplanted to other people and other times. In this way, too, one could, by praising the reason immanent in the common law, deny that the common law was simply whatever judges had decided. One could insist, on the contrary - and the eighteenth-century common lawyers increasingly did - that deeper principles underlay the common law, could be discerned through expert interpretation of it, and furnished grounds for decisions which appeared to depart from particular precedents. Such decisions furthered or were said to further values immanent in the common law - general principles 'which run through the cases', in Mansfield's phrase.

To modern positivists this appears to be a sophistical mask for judicial legislation, but this is not how it appeared then, nor is it necessarily so. Rather, underlying it are conceptions which emphasize the particularity and practicality of the judges' task, the collective nature of the publicly justified reasoning processes in which they indulge, and the wisdom of reflecting in a sustained manner on what the tradition in which one works has done in similar circumstances. It is not necessarily the mere reactionary resistance to change, and obscurantist deference to authority, that Jeremy Bentham took it to be.

5 Conclusions

The common lawyers had many commitments on which most contemporary observers would be at best agnostic. They shared, for example, a hagiographic commitment to the common law as the accumulation of the wisdom of ages. And while they did not claim that all of the common law merely stems from the customs of the people - for one of its sources is old statutes - the common lawyers saw no difficulty in claiming that it was grounded directly in the customs of the people rather than merely in the activities of the lawyers and the decisions of the judges.

Many critics have found extremely questionable this premonition of historical jurisprudence, with its homogenization of official law with social life, and of social life itself (see Jurisprudence, historical). Of course the common law has a continuing link with the common life, if only because some cases are brought by ordinary folk, and lawyers and judges are required to meditate on whatever problems are brought before them. It is one thing, however, to say that as a reactive social institution which is driven by the cases brought before it, the common law is likely to adapt over time to the ‘Conditions, Exigencies and Conveniencies of the People’; although even this is not a simple matter, for the cases that come before the courts - particularly the higher courts - are not random samples, and there are open and difficult questions about how and how much that adaptation occurs, about what law responds to in society and about what in law responds. It is another thing entirely to say that judicial law meshes directly, smoothly and constantly with popular custom. Questions abound not only about the degree of autonomy of official law from other social practices and traditions, but also about the complex and variable relationships between official and lay customs and traditions, and about the significance of social and political power in maintaining elite practices. There are also a host of other questions, for example, about what elements in plural, stratified, heterogeneous societies - including England, notwithstanding its insularity - judges’ law might be related to. While it is obvious and important, then, that law and life are intimately related, the relationships are not simple, unidirectional, unmediated or uniform. To say that the products of specialized and differentiated institutions represent a distillation of national mores and customs is to raise and to beg a host of questions of fact, morals and social theory upon which it is difficult to pronounce in general or even with regard to the long history of the common law.

Nevertheless, the common lawyers had a better appreciation than many of their successors of the complexity of social affairs, of the significance of continuity in legal life, of the need for social grounding of legal institutions, of some of the resources available to schooled participants in a traditional order, and of the inextricable relationships between continuity and continuous change that are characteristic of enduring and complex normative traditions, such as the common law. Not all of these insights were retained when the cloying hagiography of common law partisans was thrown out of philosophical discussions of law.

Common Sense School

The term 'Common Sense School' refers to the works of Thomas Reid and to the tradition of Scottish realist philosophy for which Reid's works were the main source. The ideas of the school were carried abroad - to France; and to the USA, where they were highly influential, particularly among leading academics critical of Calvinism. Interest in Reid and the tradition to which he gave rise was revived almost a century later by leading American philosophers and their students.

P. Royer Collard introduced Thomas Reid's work to France, and Victor Cousin and Théodore Jouffroy became disciples of the Scot, though they were sometimes loathe to give full credit to their mentor. Through Cousin's influence Reid's expressionist theory of art had a continuous influence throughout the nineteenth century on French aesthetics, culminating in a modern version of expressionism developed by René Sully-Prudhomme, the first recipient of the Nobel prize in literature in 1901.

John Witherspoon emigrated early in life to the United States and introduced Reid and Stewart to the young republic, where they, along with Cousin, exerted a major philosophical influence for fifty years. Their free-will agency theories were used effectively in undermining the Old School Calvinism of the Congregational and Presbyterian Churches. Among the most effective followers of Reid, Stewart and Cousin - all critics of Calvinism - were Francis Wayland (Brown University, RI), Asa Mahan (Oberlin College, OH), Henry P. Tappan (University of Michigan, MI), and Alexander Campbell (Bethany College, WV). Like Witherspoon and George Campbell before him, James McCosh emigrated from Scotland to be the president of Princeton and the last great light of the Scottish tradition in America, providing what the tradition had hitherto lacked - a realistic analysis of causality. The interest in Reid and the Scottish tradition as a whole was revived in the United States in the twentieth century by the writings of C.J. Ducasse, Roderick Chisholm, Wilfred Sellars and their students.

While it must not be thought that all the members of the tradition held identical views, there was a common core to the Scottish realistic tradition to which most of these people adhered.

According to Reid, a number of concepts and principles in daily use could not in principle be learned from experience. The concept of space, for example, could not be learned from experience since every perception presupposes it. Hence concepts and judgments which cannot be learned must be the result of nativistic epistemic input, since that is the only other alternative. The judgments supplied nativistically are numerous and constitute what Reid called the principles of common sense. The following is a small sampling of these principles: every event must have a cause; people have some degree of power over their own actions and decisions; qualities perceived by the senses must have a subject called body or substance. These principles and numerous others proclaim what is either evident or self-evident and hence require no justification other than rebuttal of criticism. Any judgment may be accepted at face value unless there is a reason to doubt it. But the only acceptable reason for doubting such a judgment would be that it conflicts with other evident judgments. Hence no discursive philosophy can throw doubt on them singly or as a class. Such judgments carry more authority than any discursive arguments that are designed to show them to be false. Moreover, common-sensical principles are inviolable because they are universally held, and they are unavoidable in the sense that denying them is pointless (in that further sense that doing so never gets rid of them). The philosopher who momentarily denies them reaffirms them in the market place or, even while denying them, acts upon them unwittingly. That Hume pointed out this state of affairs (see Hume, D. §2) was, for Reid, a very honest if self-defeating thing for a sceptic to do.

Philosophies which deny the truths of common sense principles must contain a fallacy, and the job of the philosopher is to detect that fallacy. That such philosophies must contain a fallacy follows from the fact that denying them leads to absurd consequences and from the fact that evident and self-evident judgments always constitute a better reason for keeping such principles than discursive reasons can provide for disallowing them. Since philosophers on the whole are clever reasoners we must not usually look for the fallacies in their arguments but for some faulty premise with which they begin.

An example of a faulty premise which leads to absurd consequences by rejecting an evident universal and unavoidable judgment is the premise shared by Locke, Berkeley, and Hume. Locke's premise is that the only

things of which we are directly aware are our own ideas, impressions, sensations, phenomena, or whatever else the alleged non-physical entity of direct awareness insisted upon might be called. Once granted this premise, the slippery slope from Locke to Berkeley to Hume's scepticism is inevitable. Since no sensation can in principle in any way resemble an object, Locke's representative realism is untenable and we are left with the equally untenable alternatives: Berkeley's subjective idealism, which avoids scepticism only by inconsistently allowing direct knowledge of the self, or Hume's scepticism, the claim that we can never know or have any good reason to believe that our senses ever give us reliable information. Reid found no good argument to support Locke's premise - indeed, Locke and most philosophers generally take it for granted - and he argued convincingly that Hume's 'diminishing table' argument to bolster this premise was not only not successful but proved the opposite viewpoint. Having dismissed Locke's premise, Reid offered instead his adverbial-like analysis of sensation, which construed sensation as an act of the mind and dispensed with non-physical entities altogether (Reid 1872: 245-306; 'diminishing table' argument, 303- 5). It was this aspect of the common sense tradition which re-emerged in the work of contemporary adverbial theorists like Ducasse, Chisholm, and Sellars.

Common-sense ethics

'Common-sense ethics' refers to the pre-theoretical moral judgments of ordinary people. Moral philosophers have taken different attitudes towards the pre-theoretical judgments of ordinary people. For some they are the 'facts' which any successful moral theory must explain and justify, while for others the point of moral theory is to refine and improve them. 'Common Sense ethics' as a specific kind of moral theory was developed in Scotland during the latter part of the eighteenth century to counter what its proponents saw as the moral scepticism of David Hume. Thomas Reid, the main figure in this school, and his followers argued that moral knowledge and the motives to abide by it are within the reach of everyone. They believed that a plurality of basic self-evident moral principles is revealed by conscience to all mature moral agents. Conscience is an original and natural power of the human mind and this shows that God meant it to guide our will. A deeply Christian outlook underwrites their theory.

'Common-sense ethics' refers to the pre-theoretical moral judgments of ordinary people (see Moral judgment). Moral philosophers have taken different positions on the significance of such pre-theoretical judgments with respect to moral theory. Some see our pre-theoretical judgments as the 'facts' which any successful moral theory must systematize, explain and/or justify. Others claim that moral theory should improve our common-sense moral judgments which without theory may be distorted by local prejudices and biases. 'Common Sense ethics', however, is a specific type of moral theory, which originated in Scotland during the latter part of the eighteenth century and the early nineteenth century. Thomas Reid (1785; 1788) originally developed the Common Sense moral theory in response to what he perceived as David Hume's sceptical attacks on morality. There are two central features of Hume's moral theory which Reid took to be sceptical. The first is Hume's claim that moral approval is a matter of sentiment. According to Hume (1739/40), moral approval is a sentiment, a calm form of love: when we consider persons' characters impartially, sympathy with the persons themselves and those with whom they usually associate causes us to feel love for their good qualities, and this love is moral approval. Reid interpreted Hume's claim that approval is a matter of sentiment in a way which anticipated the emotivist analysis of moral 'judgments' (see Emotivism; Hume, D. §4). According to Reid, for Hume moral approval and disapproval are merely expressions of agreeable or disagreeable feelings which are neither true nor false. When I condemn a person, I am not making a judgment about the person, but am only expressing some uneasy feeling I have (see Moral scepticism §3).

The second point which Reid found to be sceptical concerns Hume's notorious claim that 'reason is and ought only to be the slave of the passions' (1739/40: 415) (see Reasoning/rationality: practical §1; Practical reason and ethics §2). Hume argued that, strictly speaking, the idea of rational action makes no sense. Reason helps us to discern the means to our ends, but it neither selects nor ranks ends. It does not provide us with motives of either prudence or duty. Reid interpreted this as implying that reason has no say in determining our ends. Reason does not even help us to form a conception of our ends. Our ends are supplied by brute feelings.

Reid addressed both of these points in his theory of conscience: conscience is an original and natural power of the mind, common to all human beings. Reid thought this showed that God meant it to guide our wills. It is both an intellectual and active power. As an intellectual power, it enables us to intuit directly the first principles of morality. Reid thought that moral reasoning, and indeed all reasoning, must start from self-evident first principles which we perceive immediately. If we had to figure out the basic principles of morality by a process of ratiocination, as Locke maintained, morality would not be within the reach of everyone. Since morality is required of everyone, 'the knowledge that is necessary for all, must be attainable by all' (1785: 481). But only mature moral agents, those of 'ripe understanding', and free of interest, passion and prejudice, are in a position to see the self-evident moral principles. Moral education is therefore necessary.

Reid did not object to calling conscience a moral sense since he believed that a correct analysis of sensing shows that it involves judgment and so reason. Hume's mistake, according to Reid, was that he failed to see that approval is a complex act of the mind with feeling as only one component. Reid insisted that we all know the difference between feeling and judging. He granted that when I approve of someone, I experience an agreeable feeling, but claimed that this feeling is different from and dependent upon the prior judgment that the person's conduct merits esteem. Persuade me that the agent was bribed and both my esteem and agreeable feeling vanish (see Moral sense

theories).

Conscience is also an active power. Reid followed Joseph Butler in arguing that there are several distinct sources of motivation. Reid called the motives which do not presuppose judgment or reason ‘animal’ principles of action; these include our appetites, desires and affections. Those which require the use of reason are, in contrast, rational principles of action. One rational principle is our overall good. Reid argued that without reasoning we could not even form a conception of our overall good and, once we arrive at a conception of it, we necessarily seek it. It is a governing principle, to which our animal principles ought to be subordinated. The other rational principle is duty, which conscience reveals to us and which motivates us to do our duty for duty’s sake. Reid thought that the concept of duty is simple and refers to a relation between an agent and an action. Conscience’s authority, its right to govern us, is self-evident and superior to that of interest. God’s wisdom and benevolence guarantees that no agent will be a ‘loser’ by doing his duty.

Reid believed that there is a plurality of equally fundamental moral truths. Some of these concern the preconditions and range of moral judgments, for example, that only voluntary acts deserve praise. Others are substantive self-evident principles and concern our basic duties to ourselves, others and God. Reid’s list of self-evident axioms includes such principles as that we ought to act benevolently towards others, that we should treat others as we would judge it right for them to treat us, and that we owe God veneration and submission. Reid addressed an important problem which the earlier rationalists failed to see and his own followers ignored: if there is a plurality of substantive self-evident moral principles, they may come into conflict. According to Reid, the virtues, as dispositions to act according to moral principles, support and strengthen one another. But in concrete instances one principle may direct us to perform an action, while another principle forbids its performance. To use Reid’s example, ‘what generosity solicits, justice may forbid’ (1788: 639). Reid thought that in such cases we rely on self-evident priority rules, for instance, that ‘unmerited generosity should yield to generosity and both to justice’ (see Moral pluralism).

Reid’s followers, such as James Beattie and Dugald Stewart (1793; 1828) accepted the main elements of his moral theory. They agreed that the first principles of morality are self-evident and that there is a plurality of them (see Stewart, D.). They distinguished among animal and rational principles of action. They shared Reid’s belief that God meant conscience to be our guide and that it is an intellectual and active power of the human mind. On the whole they were noncritical proponents of the Common Sense moral theory, adding little to it.

Kant’s famous reaction to the philosophers of the Common Sense school was a characteristic one. Instead of answering Hume’s sceptical challenge, according to Kant (1783), they merely appealed to the common sense of humankind, without any proper insight into the question. While this may be true of Reid in his more unguarded moments and of his disciples more generally, the Common Sense moral theory was influential not only in France and England but also in the US. By the mid-nineteenth century, William Whewell’s version of rational intuitionism became dominant (1845), overshadowing the Common Sense moral theory.

There is a relation between common-sense ethics and the Common Sense moral philosophers: the Common Sense moral philosophers trusted the conscience of ordinary people. Philosophical ethics, although useful in bringing self-evident moral truths to light and systematizing them, has a limited role to play in revising them. If there is a conflict between ‘the practical rules of morality, which have been received in all ages’ and those advanced by theorists, as Reid says, ‘the practical rules ought to be the standard by which the theory is corrected’ (1788: 646). But the Common Sense moral philosophers’ confidence in the judgments of ordinary people sprang from their conviction that conscience is ‘the candle of the Lord set up within us’ (Reid 1788: 597). It is grounded in the belief that God gave us the capacity not only to know what we ought to do but also to do it.

In ch. 2 of the essay, 'Whether Morality be capable of demonstration', Reid argues against the Lockean view that we arrive at the first principles of morality by means of demonstrative reasoning.)

Reid, T. (1788) 'Of the Rational Principles of Action' and 'Of Morals', in *Essays on the Active Powers of Man*; in W. Hamilton (ed.) *Works*, Edinburgh, 1846-63, 2 vols; repr. Hildesheim: Georg Olms Verlagsbuchandlung, 1967.(The page numbers given for the quotations cited in the above entry come from Hamilton's edition. This work contains Reid's moral theory. It also includes Reid's libertarian account of freedom. Although Reid often misinterprets Hume, some of his criticisms of Hume are insightful. Reid thought that Hume uncritically accepted the theory of ideas and that his mistakes may be traced to this. Includes an appendix in which Hamilton explains the idea of common sense.)

Schneewind, J.B. (1977) *Sidgwick's Ethics and Victorian Moral Philosophy*, Oxford: Clarendon Press, ch. 2. (Contains a clear, concise and informative discussion of the main elements of Reid's moral psychology, his account of the liberty of the will, and justice. Also included is a short but helpful discussion of Reid's followers who wrote about morality.)

Stewart, D. (1793) 'Of the Active and Moral Powers of Man', in *Outlines of Moral Philosophy*; in W. Hamilton (ed.) *Collected Works*, Edinburgh: T. & T. Clark, Constable 1854-77; repr. Westmead: Gregg International, 1971. (Based on his lectures, Stewart wrote this for the use of students at Edinburgh. This work includes a discussion of the various springs to action, the origin of our moral ideas, and our duties to God, others and ourselves. An appendix contains an outline of his political theory.)

Stewart, D. (1828) *Philosophy of the Active and Moral Powers of Man*, ed. and abridged by J. Walker, Boston, MA: Phillips, Samson and Co., 1868.(An expanded version of the *Outlines*, this work contains a critical survey of British modern moral philosophy. Stewart argues against Hobbes and others that the sense of duty cannot be reduced to self-love. He opposes Paley's associationism and Bentham's utilitarianism. The influence of Reid is especially evident, as well as that of Cudworth, Shaftesbury, Butler and Price. Stewart tends to avoid appeals to a common sense.)

Whewell, W. (1845) *The Elements of Morality, Including Polity*, London: J.W. Parker, and New York: Harper & Bros, 2 vols.(Whewell's account of rational intuition is sometimes closer to that of Kant's than Reid's. He emphasizes that intuition is an activity of reason and not just a passive perception of first principles.)

Common-sense reasoning, theories of

The task of formalizing common-sense reasoning within a logical framework can be viewed as an extension of the programme of formalizing mathematical and scientific reasoning that has occupied philosophers throughout much of the twentieth century. The most significant progress in applying logical techniques to the study of common-sense reasoning has been made, however, not by philosophers, but by researchers in artificial intelligence, and the logical study of common-sense reasoning is now a recognized sub-field of that discipline.

The work involved in this area is similar to what one finds in philosophical logic, but it tends to be more detailed, since the ultimate goal is to encode the information that would actually be needed to drive a reasoning agent. Still, the formal study of common-sense reasoning is not just a matter of applied logic, but has led to theoretical advances within logic itself. The most important of these is the development of a new field of 'non-monotonic' logic, in which the conclusions supported by a set of premises might have to be withdrawn as the premise set is supplemented with new information.

The formal study of common-sense reasoning is a field in which the concerns of philosophy and artificial intelligence converge. From a philosophical point of view, it is motivated by a popular approach to the philosophy of mind - known as the 'language of thought' hypothesis - that postulates a domain of mental representations as the primary bearers of meaning, and then analyses cognition as the rule-governed manipulation of these representations. In order for an approach along these lines to be useful, some account must be provided of the structure of the internal representations, and of the rules governing their manipulation (see Language of thought).

These issues have been studied extensively within cognitive psychology, of course. Here, the idea is to focus on an existing system capable of intelligent behaviour in a wide range of circumstances - a human being - and to attempt to infer the symbolic processes underlying this intelligence. But the issues are studied also within the area of artificial intelligence, and from a perspective that offers a different kind of illumination: the goal here is to build an intelligent system, rather than attempting to discover the structure of a system that already exists. Although the performance exhibited by the artificial systems designed to date is significantly less impressive than that of humans when evaluated across a broad range of circumstances, the symbolic processes underlying the behaviour of these systems are at least well understood.

Among the various research methodologies that have emerged within artificial intelligence, one of the most powerful is the logic-based approach first advanced by John McCarthy; and it is primarily this approach that has motivated the formal study of common-sense reasoning. In fact, the logic-based approach in artificial intelligence has much in common with the project of formalizing mathematical and scientific reasoning that has been carried on throughout the twentieth century. Within artificial intelligence, the idea is that much of the knowledge necessary for achieving intelligent action even in everyday situations can be represented in a machine through the formulas of some logical language, and that the reasoning tasks underlying this intelligence can then be accomplished by means of logical deduction.

Both the idea of using logic as an underlying representation language for artificial intelligence and the emphasis on formalizing common-sense knowledge are present even in McCarthy's very early work (for example, McCarthy 1959), but the project receives its clearest articulation in a paper jointly authored by McCarthy and Patrick Hayes (1969), which isolates the task of defining 'a naïve, common-sense view of the world precisely enough to programme a computer to act accordingly'.

Much of the work now produced within artificial intelligence on the topic of formalizing common-sense reasoning is similar to what one finds in philosophical logic - attempts to adapt or generalize logical techniques to apply to some new area - and there is now a good deal of interaction between these two fields. Still, the research that takes place within artificial intelligence has a somewhat different character from standard philosophical logic. For one thing, the matter of implementation is always in the background, and sometimes in the foreground; but even apart from that, the studies generated within artificial intelligence are often focused on very detailed representational problems that would seem peculiar to a philosopher. It would not be unusual, for example, to find a research project in artificial intelligence with the goal of representing what an agent would have to know about the objects

in their kitchen in order to prepare a meal.

This kind of detailed work is necessary, of course, since the ultimate goal is to encode information in such a way that it could actually be used to drive a reasoning agent. Still, it is not as if the project of providing a logical representation of common-sense knowledge were simply a matter of applied logic. In fact, the problems presented by the task of representing this kind of information explicitly have led to a number of theoretical advances within logic itself: the most important of these is the development of the new field of 'non-monotonic' logic.

In most standard logics, the addition of new information to a given set of premises might lead us to draw new conclusions, but never to withdraw conclusions already reached. The set of consequences of a given set of premises is thus said to grow monotonically as the premise set grows: the consequence set can only increase, never decrease, as the premise set is supplemented with new information. A non-monotonic logic is simply a logic in which this property fails - a logic in which the addition of new information to a given premise set might force us to retract some conclusion drawn from the original set of premises (see Non-monotonic logic).

The study of non-monotonic logics within artificial intelligence was motivated by the realization that much of our common-sense knowledge concerns defeasible information - generalizations subject to exceptions, such as 'Birds fly' or 'Things remain where you put them'. Of course, philosophers had always known that these defeasible generalizations could not be represented naturally in ordinary logic: the statement 'Birds fly', for example, cannot be represented by a formula of the form $\forall x(Bx \supset Fx)$. But it was not until the practical need arose for reasoning with defeasible statements such as these that serious attention was focused on the problem; and it then became apparent that the appropriate notion of defeasible consequence would have to be non-monotonic.

To take a standard example, given only the information that Tweety is a bird and that birds tend to fly, it is natural to conclude defeasibly that Tweety flies. But if this premise set were supplemented, consistently, with the additional information that Tweety does not fly (perhaps Tweety is a penguin), it would then seem reasonable to withdraw our initial conclusion.

The monotonicity property flows from assumptions that are deeply rooted in both the proof theory and the semantics of most ordinary logics. From a proof-theoretic point of view, this property follows from the fact that a proof based on a set of premises also counts as a proof based an expansion of the same set of premises; from a semantic point of view, the property results from the assumption that the models of a set of premises are models also of any of its subsets. Because the features underlying the monotonicity property are so basic to the conception of most standard logical systems, researchers concerned with non- monotonic reasoning have been led to explore fundamentally new ideas in both proof theory and semantics.

The first proof-theoretic treatment of non-monotonic reasoning is found in Raymond Reiter's default logic (1980), which supplements ordinary logic with new rules of inference, known as 'default rules'. The semantic approach to non-monotonic reasoning was first explored in McCarthy's own theory of circumscription (1980).

Because of its intrinsic interest and practical importance, the study of non-monotonic logic has grown into a significant area of research. The fixed-point and minimal model approaches pioneered by Reiter and McCarthy are still the best-known and most widely applied techniques in non-monotonic reasoning, but a number of other approaches have been explored as well; a series of articles surveying these different approaches can be found in Gabbay *et al.* (1994). In recent years, the techniques developed within the field of non-monotonic logic have begun to find applications also to a number of philosophical issues, such as the understanding of *ceteris paribus* clauses in scientific generalizations and the formalization of *prima facie* obligations.

Commonsensism

'Commonsensism' refers to one of the principal approaches to traditional theory of knowledge where one asks oneself the following Socratic questions: (1) What can I know?; (2) How can I distinguish beliefs that are reasonable for me to have from beliefs that are not reasonable for me to have? and (3) What can I do to replace unreasonable beliefs by reasonable beliefs about the same subject-matter, and to replace beliefs that are less reasonable by beliefs that are more reasonable? The mark of commonsensism is essentially a faith in oneself - a conviction that a human being, by proceeding cautiously, is capable of knowing the world in which it finds itself.

Any inquiry must set out with some *beliefs. If you had no beliefs at all, you could not even begin to inquire. Hence any set of beliefs is better than none. Moreover, the beliefs that we* do *find ourselves with at any given time have so far survived previous inquiry and experience. And it is psychologically impossible to reject everything that you believe. 'Doubting', Peirce says, 'is not as easy as lying'. Inquiry, guided by common sense, leads us to a set of beliefs which indicates that common sense is on the whole a reliable guide to knowledge. And if inquiry were not thus guided by common sense, how would it be able to answer the three Socratic questions with which it begins?*

1 Background: Reid and Peirce

The term 'commonsensism' was introduced by Charles Sanders Peirce who was concerned to contrast his own 'critical commonsensism' with the views of Thomas Reid and with those of the other members of the Scottish Common Sense school of philosophy. According to Reid, the 'principles of common sense' are intuitive truths that all sane people accept when they are not doing philosophy. They are no less reasonable than the truths of logic and mathematics.

Reid is most persuasive in criticizing those philosophers who reject the principles of common sense. He calls our attention to the extremes of British empiricism, culminating in the absurdities of Hume's empirical system. These alleged absurdities include the following: we cannot know anything about the past; we cannot know whether there are any material things; and we cannot even know that we ourselves exist. Reid observes:

> A traveller of good judgment may mistake his way, but when it ends in a coal-pit, it requires no great judgment to know that he hath gone wrong, nor perhaps to find out what misled him'. The committed empiricist who is not yet prepared to abandon his extreme epistemological views may point out that Reid cannot demonstrate, to the empiricist's satisfaction, that the empiricist is not in a delirium. 'But how does he know that he is not in a delirium? I cannot tell; neither can I tell how a man knows that he exists. But, if any man seriously doubts whether he is in a delirium, I think it is highly probable that he is, and that it is time to seek for a cure.
>
> (Reid [1764] 1854: 107)

A somewhat more patient and difficult response may be found in the critical commonsensism of Peirce, which may be thought of as a refinement upon the views of Reid. Peirce says that his own view 'arises out of a contrite fallibilism, combined with a high faith in the reality of knowledge, and an intense desire to find things out' (Peirce 1931-5: 1.14) (see Fallibilism).

2 Critical commonsensism: a systematic treatment

'The slogans are impressive enough,' one may say, 'but how are they to be applied?' In setting out, one presupposes that, by contemplating various possible beliefs, we can find out that some of them logically imply others, that some contradict others, that some are such that they serve to confirm others (they make the others probable) and that some are such as to disconfirm others (they make the others improbable). Probability, as Peirce conceives it, is 'a thing to be inferred upon evidence'.

Two quite different procedures are involved. The first is that of ridding ourselves of beliefs that we should not have. The second is that of reconstruction - that of 'building anew'. We may call the second procedure 'the road back'. Descartes distinguishes the two steps in the first of his *Meditations*: 'I was convinced that I must once for all seriously undertake to rid myself of all the opinions which I had formerly accepted, and commence to build anew from the foundation'. Critical commonsensism, therefore, is a version of foundationalism (see Foundationalism).

To see how commonsensism is applied in the theory of knowledge, we should consider the ‘building anew’ that is involved in the road back. Having some faith in ourselves, we start out with our native common sense - with what we find ourselves inclined to believe. Where else, after all, could we start out? If, like Peirce, we accept critical commonsensism, we will make this assumption: the mere fact that we find ourselves believing one thing rather than another is itself a *prima facie* reason for believing that thing. One way to improve upon this mass of uncritical beliefs is to sift it down and try to cast away the things that should not be there. If we find a set of beliefs that contradict each other, we will try to sift it down in such a way that the remaining set is not contradictory. If we then find that the remaining set disconfirms some of its members, then we will proceed in analogous fashion, in the hope that the surviving set will not thus disconfirm any of its members.

We also appeal to the experiences of perceiving and remembering. Suppose you think that you are perceiving a sheep. That you think you are perceiving a sheep gives some *prima facie* justification for that belief. And at this stage of the road back, there may be still more to be said for the belief. If the belief is confirmed by the set of other beliefs that has so far survived your critical scrutiny, then it is more reasonable than any belief not so confirmed.

What has been said about perceiving may also be said, *mutatis mutandis*, about remembering. Traditional empiricism, Peirce points out, is not adequate to the epistemic status of memory (see Empiricism). Still another source of epistemic respectability is the possibility of concurrence (also called ‘coherence’ and ‘mutual support’). A set of beliefs may be said to concur, or to be related by mutual support, provided that any of its members is confirmed by the conjunction of all the others. If we find such a set among the beliefs that we still have, then we may say that the whole now has a still greater degree of epistemic respectability (see Knowledge and justification, coherence theory of).

In summarizing his approach to the theory of knowledge, Peirce calls attention to ‘one of the most wonderful features of reasoning and one of the most important philosophemes in the doctrine of science, of which, however, you will search in vain in any book I can think of: namely, that reasoning tends to correct itself, and the more so, the more wisely its plan is laid. Nay, it not only corrects its conclusions, it even corrects its premises’ (Peirce 1931-5: 5.575).

3 Commonsensism and metaphysics

The ‘defence of common sense’ associated with G.E. Moore should not be considered as being primarily an attempt to deal with the problems of the traditional theory of knowledge. It is intended, rather, as a corrective to what Moore felt were some of the excesses of the metaphysicians of his day, particularly those in the tradition of absolute idealism (see Moore, G.E. §§2-3). Some of these philosophers, for example, tried to prove that there is no valid distinction between appearance and reality. In lectures on this topic, Moore would refute such views in the following way. He would hold up his hand, saying ‘Here is a hand’, and he would then point out that this obvious fact was inconsistent with the proposed theory about appearance and reality. If their reasoning were sound, then they would not be justified ‘in believing that this is a hand’. Some of these philosophers had also felt that they could prove that ‘time is unreal’. Moore calls to their attention what, apparently, many of them had not noticed - that their thesis has the absurd consequence that no one ever knows whether or not they had their breakfast before having their lunch. Such refutations met with considerable indignation but not with any very convincing rejoinders.

Communication and intention

The classic attempt to understand communication in terms of the intentions of a person making an utterance was put forward by Paul Grice in 1957. Grice was concerned with actions in which a speaker means something by what they do and what is meant might just as much be false as true. He looked for the essence of such cases in actions intended to effect a change in the recipient. Grice saw successful communication as depending on the recognition by the audience of the speaker's intention. Since then there have been many attempts to refine Grice's work, and to protect it against various problems. There has also been worry that Grice's approach depends on a false priority of psychology over semantics, seeing complex psychological states as existing independently of whether the agent has linguistic means of expressing them.

1 Grice's theory

The classic attempt to understand communication in terms of the intentions of a person making an utterance was put forward by Paul Grice in his 1957 article. Grice takes as his subject what he calls 'non-natural meaning' (meaning_{NN}), which he contrasts with the wider class of cases of natural meaning in which we say, for instance, that 'those spots mean measles' or 'those clouds mean rain'. It cannot be true that those spots mean measles but the patient has not got measles; meaning is simply a correlation or signalling. Whereas Grice is concerned with actions in which a speaker (or, in general, an agent) means something by what they do and what is meant might just as well be false as true. Here too he makes a distinction: between a wider class of actions that predictably cause a recipient to believe something, and a narrower class of actions that not only may cause the belief that *p*, but also themselves mean that *p*. The wider class would include such actions as leaving photographs around, expecting the recipient to believe that the events shown had happened. The narrower class should take us somewhere near the domain of linguistic communication.

Grice looks for the essence of such cases in actions intended to effect a change in the recipient. He eventually located the difference in the manner in which the change in belief is expected to come about. In the wider class, the action may simply be a natural sign of the state of affairs, but in the narrower class of non-natural meaning there is an element of reflexivity involved, since the intended mechanism, through which the recipient is expected to come to the belief, is that the agent is recognized as acting with the intention that the recipient come to believe it: it is only if the agent's intention is recognized that the change in belief will ensue. So, for example, deliberately ignoring someone in the street might be said to mean_{NN} that the agent is angry with the recipient, because getting the recipient to believe this depends upon their recognizing the intention with which the action was performed. Grice proposes that '*A* meant_{NN} something by *x*' is roughly equivalent to '*A* uttered *x* with the intention of inducing a belief by means of the recognition of this intention'. He sees successful communication as requiring recognition of the speaker's intention in communicating. Of course, the account could be extended to speech acts other than assertion: for example, intentions to get people to perform actions or supply information can be used to fix what is meant by imperatives and questions.

Armed with an account of the speaker's meaning on an occasion, Grice goes on to propose that 'the utterance *x* meant something' is roughly equivalent to 'someone meant something by *x*'. For a sentence to mean something 'timelessly' is for people in general to use it to mean that thing. We can thus progress from an account of communication in a 'one-off' case to a more general account of the kind of meaning possessed by the sentences of a public language.

2 Reactions

Grice's short article spawned a huge literature, and various modifications were suggested. One is that it may not be quite right to identify the speaker's intention as one of changing the hearer's belief. I may say that *p* without caring whether my hearer accepts or indeed already believes that *p*. A change in belief might be one effect of my utterance, but it is not always one I intend (in the terms introduced by Austin, it is a 'perlocutionary' effect), whereas we are looking for a characterization of what a speaker is doing in uttering anything (the 'illocutionary' act; see Speech acts §1). It seems rather that the only reliable intention behind an utterance is that the speaker intends the hearer to understand something by it, not necessarily to believe it or react to it in any other

way. But already it is a matter of fine judgment whether this is important, and, after all, one can say things with the intention that the hearer not even understand them, for example when showing off one's grasp of some technical term. Certainly, a defence of Grice would go, once the whole social practice of communication with language is in place, we can say things with the most devious of intentions. Nevertheless, it may be true that the central or paradigm case is that of imparting information, and indeed any account that fails to put this function of language at the centre risks distortions of its own. So Grice may simply be following the proper path by concentrating upon the central or basic case and hoping that deviations will become explicable in the light of what is said about it.

A more elaborate debate queried whether Grice's conditions are sufficient for meaning. It concentrates on cases where there is an element of deceit. As Bennett puts it, 'in real communication everything is open and above board' (1976: 126), but a range of cases suggest that Grice's conditions could be met while there are hidden and devious intentions around. Grice's conditions could be satisfied while, further up the hierarchy of intentions, I have the intention that you misunderstand something about the situation. Complex counterexamples of this structure were rapidly concocted. However, what Grice called 'sneaky intentions' can be blocked by a number of strategies. One such is to require that all the speaker's intentions be known to the hearer, and another is that the intentions in question should be 'mutually known', where this means that the hearer knows the speaker's intentions, the speaker knows that the hearer knows, the hearer knows that the speaker knows…and so on.

There is a cost to piling up the reflexive intentions with which speakers are credited, for it is easy to wonder whether there is a psychological reality to these complex layers of intention, or whether they are simply an artefact of the theory. In fact, some unease arises when we realise that Grice's approach requires that the reflexive intention - the intention that the hearer's belief be modified by means of their recognition of my intention in speaking - be typically present throughout the field of linguistic communication. It would seem to be to overload the psychology of the young child or not-very-aware adult to credit them with intentions of such complexity: typical speakers, we might say, just do not know or care *how* their messages get across, so long as they do. Certainly a strategist faced with a hitherto unknown type of problem of communication may do something with the hope that the intention with which they do it is recognized, but this seems to be a sophisticated plan for coping with precisely the kind of situation where normal communication has broken down.

This kind of thought suggests that Grice is too much concerned with one-off cases. At least in typical cases of communication we are not involved in one-off strategies, but can rely upon the conventional meanings of our terms. (For Grice himself, as we have seen, the existence of these conventions would simply be the existence of enough people inclined to use a term to effect communication in enough cases.) While reflexive intentions may be necessary to solve new problems of communication, as when we confront someone with whom we share no language, it may be that they drop out of the picture when a rule-governed or conventional medium of communication is available: it may be that reliance on conventions and rules supplants the mechanism of recognizing the speaker's intention, rather than supplementing it. Once we have language I do not have to know even whether you intended me to understand you in order to know what you said. Similarly, there may be sentences whose typical use is not to convey the messages that their strict and literal meanings suggest, but nevertheless, when uttering one of them, one can be held to have said whatever it is that its strict and literal meaning identifies. In short, a conventional and deeply normative system (that is, one in which the speaker is *liable* to be held to have said things, regardless of what was intended) takes on a life of its own, independent of the detailed case-by-case intentions of participants.

Behind this objection there lies the deeper unease that Grice's approach sets things up so that the speaker has intentions of considerable complexity, and we then try to understand meaning and linguistic communication given so much rich psychology. Whereas a permanent strand in modern philosophy of language has been to try to identify the mastery of language with the ability to have thoughts (or, at least, thoughts of this kind of complexity) at all. From this standpoint it may seem perverse arbitrarily to enrich the psychology of the actors, and on that basis to explain their use of sentences as vehicles of their given, antecedent intentions. You cannot intend, the thought goes, without representing to yourself what you intend, and typically this will be by using the best representative medium known to us, which is our natural language. In forming an intention we typically speak to ourselves, saying that we will do this or that, and if this process is itself seen as a kind of internal communication then intentions are not suitable for giving an analysis of communication in general. So we should be thinking of social communication as one of the activities that makes possible the enriched psychology that we find in

participants in conversational exchanges. The problems in this area are, however, deeply intractable. Some philosophers, notably John Searle (1983), insist that the 'intentionality' of language (that is, its directedness or power to represent absent or merely possible states of affairs) must be understood as being derived from a more fundamental power of the 'mind/brain'; in such a scheme there is no problem with Grice's direction of attack. To others it merely mystifies things to postulate intentional powers in the mind/brain, and our capacity to represent absent states of affairs to ourselves must be seen as essentially linguistic, since language is the only representational system that we actually know anything about.

A final radical criticism is that Gricean proposals try to secure openness in communication by adding to the speaker's intentions. But, it has been argued (Meijers 1994), openness cannot be secured that way. It is a matter of a relationship between the speaker and hearer, not a one-way matter of the speaker having sufficiently open intentions. A speaker must not only have the intention to be open, but there must also be a commitment to being open (and liability to penalty if they are not). Arguably this takes us into the domain of collective intentions; ones based on an understanding between the different parties about what they, collectively, are trying to do. The relation between speaker and hearer, by such an account, is more like that between us when we together plan that *we* sing a duet, than when I unilaterally intend that *I* do something with some effect on you. Again, there are various proposals about the nature of such common intentions, and whether they reduce to a kind of aggregate of individual intentions.

3 Prospects and alliances

Sir Peter Strawson (1971) detected a 'Homeric opposition' between followers of Grice and philosophers of language, such as Davidson, who put the notion of a truth-condition at the centre of their picture. It is fair to say that this opposition has softened in the intervening years. Clearly there is no formal contradiction between supposing that a remark in the mouths of members of some community means that *p* if and only if there exists a practice of using it with the intention of communicating that *p*, and saying that the same remark means that *p* if and only if it represents the state of affairs that *p*, or has the truth-condition that *p*, or would be interpreted by an ideal interpreter as saying that *p*. The opposition is a question of whether we give priority to representation over communication, or vice versa. If we think of sentences possessing meaning by way of some kind of accord with things and facts, then their role in communication will seem a kind of bonus; if we think of the seamless way in which linguistic behaviour is woven into communication (and other activities involving the world) then we will reject any appeal to basic representative powers of elements of the 'mind/brain', in favour of a clearer understanding of the representative powers of the whole person, here meaning the linguistically active, socially embodied person communicating with others of the same nature.

The perennial importance of Grice's work is that intention and communication cannot be separated for long. If I intend to tell you that the cat is sick, we have not communicated unless this is how you take my utterance. If I intend a remark ironically or condescendingly, then we have not communicated unless you understand the irony or the condescension. And there is a limit to the possibility of unintended meaning: although on an occasion someone may mean something by an utterance that they did not intend, or fail to mean something that they did intend, such occasions are essentially parasitic. If they occur too often, then the conventions shift, and the meaning of the remark in the language realigns itself with the way the speakers intend it. There is no separating semantics and psychology, but there is the perennial question of priority. The strange and intriguing interdependency of intention and language seems to be two-way: our words can convey no more than we intend by them, but we ourselves can intend only what our words will carry.

Further work on these topics clearly requires a better understanding of whether meaning is essentially social. Work on rule-following has sometimes issued in the view that it must be so, and that determinate meaning only emerges in a fully social, normative practice in which the applications of words are routinely subject to criticism and correction. If this kind of thought can finally be defended, then Grice's programme will have been thoroughly vindicated, in its direction if not in every detail.

Communicative rationality

The concept of 'communicative rationality' is primarily associated with the work of the philosopher and social theorist Jürgen Habermas. According to Habermas, communication through language necessarily involves the raising of 'validity-claims' (distinguished as 'truth', 'rightness' and 'sincerity'), the status of which, when contested, can ultimately only be resolved through discussion. Habermas further contends that speakers of a language possess an implicit knowledge of the conditions under which such discussion would produce an objectively correct result, and these he has spelled out in terms of the features of an egalitarian 'ideal speech situation'. Communicative rationality refers to the capacity to engage in argumentation under conditions approximating to this ideal situation ('discourse', in Habermas' terminology), with the aim of achieving consensus.

*Habermas relies on the concept of communicative rationality to argue that democratic forms of social organization express more than simply the preferences of a particular cultural and political tradition. In his view, we cannot even understand a speech-act without taking a stance towards the validity-claim it raises, and this stance in turn anticipates the unconstrained discussion which would resolve the status of the claim. Social and political arrangements which inhibit such discussion can therefore be criticized from a standpoint which does not depend on any specific value-commitments, since for Habermas achieving agreement (*Verständigung*) is a 'telos' or goal which is internal to human language as such. A similar philosophical programme has also been developed by Karl-Otto Apel, who lays more stress on the 'transcendental' features of the argumentation involved.*

1 Instrumental and communicative rationality: Habermas and the Frankfurt School

Jürgen Habermas, the leading thinker of the second generation of the Frankfurt School, introduced the concept of communicative rationality in order to correct what he perceives to be the 'normative deficit' in the work of earlier thinkers in this tradition. This deficit consists in the lack of any philosophically perspicuous grounding for their critique of modern society. The thought of the Frankfurt School before Habermas, classically summarized in Theodor Adorno and Max Horkheimer's *Dialectic of Enlightenment* (1944), viewed social relations within the most advanced capitalist societies as being almost entirely shaped by the demands of 'instrumental reason'. Strongly reminiscent of Max Weber's 'purposive rationality' (*Zweckrationalität*), the concept of instrumental reason refers to the capacity to maximize efficiency in the control of objective processes through a knowledge of the determinants of such processes. For Adorno and Horkheimer the predominant institutionalization of this *aspect* of reason, reflected in its pervasive philosophical equation with reason as such, has socially disastrous consequences. It leaves the ends to be collectively pursued beyond the scope of rational determination, and gives rise to a 'totally administered society'. At the same time however, as Habermas repeatedly complains, the earlier Critical Theorists propose no alternative broader conception of reason, from the standpoint of which the restriction of reason to its instrumental aspect could be coherently criticized (see Frankfurt School; Critical theory).

The contrast between instrumental and communicative rationality, which represents Habermas' attempt to remedy this situation, is anchored in the philosophical anthropology systematically presented in *Knowledge and Human Interests* (1971). Here Habermas argues that any society, in order to reproduce itself, must be capable both of productive exchange with nature (in the form of labour), and of the communicative coordination of collective activities. Labour gives rise to concepts which articulate a 'technical interest' in instrumental control, whereas the need for agreement generates the distinct categorial framework of a 'practical interest' in hermeneutic understanding. In later writings Habermas specifies that participants in 'communicative action' must be capable of regarding the statements raised in the course of discussion from the standpoint of their *validity*, and must possess an implicit knowledge both of the appropriate procedures for settling disputed validity-claims and of the (invariably counterfactual) conditions under which following such procedures would produce an objectively correct result. Such knowledge is mobilized, for example, when discovery of covert coercion renders a previously achieved consensus invalid.

In the Western philosophical tradition, the concept of rationality has long been connected with the ability to reflect on and give grounds for one's beliefs and the actions they inform. However, in modern philosophy, it is often only beliefs capable of guiding goal-oriented action which are considered as candidates for rationality. Against this,

Habermas argues that the type of action oriented towards reaching agreement in language is irreducible to that which is oriented towards successful intervention in the objective world. The illocutionary aims of speech acts can only be achieved through cooperation, based on a free acceptance by others of the validity-claims raised by the speaker, which cannot be reduced to a causally producible effect. Hence the ability to achieve consensus by offering grounds reflects a distinct form of rationality which ‘inhabits everyday communicative practice’, and which Habermas therefore describes as ‘communicative rationality’.

With regard to the problem of grounding a critical social theory, two aspects of Habermas’ proposal are significant. First, Habermas extends the scope of validity beyond ‘truth’ (*Wahrheit*). He argues that claims to normative rightness (*Richtigkeit*), typically moral or legal claims, are in principle susceptible of the same form of resolution through discussion as cognitive claims. There can thus be an equivalent of truth in practical matters, although Habermas admits that the status of a claim to ‘sincerity’ (*Wahrhaftigkeit*) cannot be resolved through discussion. (An additional claim, concerning the ‘intelligibility’ (*Verständlichkeit*) of one’s utterance, is only discussed sporadically by Habermas, and is perhaps best considered as a *precondition* of these principal validity-claims.) Second, canons of argument are themselves not merely relative to specific cultural and institutional contexts. Whenever we engage in argumentation, Habermas proposes, we must implicitly assume (however counterfactually) that the conditions of an ‘ideal speech situation’, in which the ‘unforced force of the better argument’ would indeed ultimately triumph, have been fulfilled, otherwise discussion would lose its point. Such a speech situation would be characterized by the equal right of all participants to raise issues, ask questions, pose objections and so on, and therefore provides a normative yardstick against which current decision-making procedures can be critically assessed. In particular, the widespread dominance of the functional requirements of ‘social systems’ such as the market economy and modern bureaucracy can be seen as embodying a one-sided ‘rationalization’ which suppresses the rational potential of those democratic principles which are equally fundamental to modernity.

2 Objections to Habermas’ approach

The concept of communicative rationality faces objections from a variety of quarters. If such rationality is to represent more than the ability to adhere to culturally specific canons of argumentation, then Habermas must show the universal necessity of those pragmatic presuppositions of communication which form the ideal speech situation. The first step towards this is to argue for an internal relation between meaning and validity. Habermas contends that ‘ we understand a speech-act when we know what makes it acceptable’ ([1981] 1984: 400), where acceptability refers to intersubjective recognition of validity and not to correspondence with a reality whose structure would supposedly be given prior to language. He then draws the conclusion that ‘ an orientation towards the possible validity of utterances belongs not just to the pragmatic conditions of reaching understanding, but to the understanding of language as such’ (1988: 76).

However, Habermas’ account of the preconditions for grasping linguistic meaning may be implausibly strong. Herbert Schnädelbach (1991), for example, has objected that to understand what makes an utterance acceptable does not require one to take a stand on whether it is, in the present instance, valid. We can observe communicative action - the exchanging of reasons - from a third-person perspective without being drawn into the process of judging validity-claims, so that a normative standpoint is not internal to the very application of the concept of communicative rationality. In reply, Habermas has argued that even in apparently unfavourable cases, such as a sudden burst of laughter during a speech, we cannot understand the laughter without knowing if it is genuine or not (and thus a valid ‘utterance’), and this involves *assessing* the grounds for it. The methodological suspension of our spontaneous yes/no attitude towards validity-claims merely indicates that the task of interpretation is being postponed.

A further major objection to Habermas’ views has been raised by Albrecht Wellmer, among others. It is that there may indeed be certain idealizations which function as necessary pragmatic presuppositions of linguistic communication, but that the notion of an ideal speech situation represents an ‘objectivistic misinterpretation’ of these. This is because an ideal speech situation, exempt from the fallibility, opacity and temporality of human language, would be beyond the conditions which make communication itself necessary and possible. To regard the striving for such a situation as morally incumbent upon us would be to regard us as obliged to attain the impossible, which is absurd. According to Wellmer (1986), communication indeed relies upon ‘performative

idealizations' (for example, the conviction that the reasons we have for a claim are sound and will stand the test of time), but to transform these idealizations into an ideal to be practically pursued is to fall prey to a 'dialectical semblance' (*Schein*). Habermas, however, continues to maintain that it is meaningful to idealize forms of communication, just as we idealize physical measurements; in other words, to anticipate the full realization of conditions we must already presume to hold to some degree when engaged in serious argumentation.

Other critics have focused on Habermas' claim that reaching an understanding can be seen as the primary function of language, to which we are implicitly committed as soon as we speak. Thinkers influenced by post-structuralism, in particular, have objected that the commitment to achieving consensual truth cannot, except by begging the question, be considered more fundamental than playful, ironic or fictional uses of language. More generally, it is contended that an essential semantic instability of language, or the relativity of meaning to context, undermines even the assumption that identical meanings are exchanged in communication.

In reply to this, Habermas suggests that joking, playful, ironic and fictional uses of language depend on an intentional confusion of contrasting modes correlated to validity-claims (being/illusion, is/ought, essence/appearance), which is simultaneously seen through as such. These uses therefore depend on a prior recognition of the distinctions between validity dimensions. Habermas also emphasizes that belief in the identity of communicated meanings has no *metaphysical* status, but is merely a pragmatic presupposition which can (indeed must) be unproblematically relied on, up to the point where communication actually breaks down.

3 Apel's approach and his critique of Habermas

Habermas' account of communicative rationality has developed over the years in tandem with that of his Frankfurt colleague Karl-Otto Apel. However, Apel's programme is more strongly connected to the tradition of transcendental philosophy (Apel prefers the term 'transcendental pragmatics' to Habermas' 'universal pragmatics' for the general theory of communicative competence). The key conflict between Apel and Habermas concerns their attitude to the possibility of an 'ultimate grounding' (*Letztbegründung*) for a universalistic moral standpoint. In a critical essay (1992), Apel contends that Habermas is mistaken to play down the 'transcendental difference' between empirically testable reconstructions of communicative competence and philosophical reflection which reveals the unconditional validity of certain basic presuppositions of argumentation. Apel sees here a confusion which leads to paradoxical consequences - for example, that the 'principle of fallibilism' (the principle that no empirical consensus can be immune to revision) must itself be regarded as fallible. Habermas, however, replies that the normative preconditions of communication should be considered only as 'factically indispensable': they cannot be imagined as inoperative given our human socio-cultural form of life. To show this, however, we do not need to set philosophical truths in a position of qualitative precedence over knowledge obtained by scientific methods.

The concept of communicative rationality has thus been, and continues to be, the subject of intense debate. These reflect that fact that the project of defining a concept of rationality more encompassing that instrumental rationality, one internally connected to the idea of *reciprocal* and *egalitarian* relations between human beings, has deep roots in the German philosophical tradition since Kant. Because of this, whatever future transformations this project may undergo, it is unlikely to be entirely abandoned.

Communism

Communism is the belief that society should be organized without private property, all productive property being held communally, publicly or in common. A communist system is one based on a community of goods. It is generally presented as a positive alternative to competition, a system that is thought to divide people; communism is expected to draw people together and to create a community. In most cases the arguments for communism advocate replacing competition with cooperation either for its own sake or to promote a goal such as equality, or to free specific groups of people to serve a higher ideal such as the state or God.

The word *communism* appears to have first been used in the above sense in France in the 1840s to refer to the ideas of thinkers such as Françoise Émile Babeuf (1760-97) and Étienne Cabet (1788-1856), both of whom advocated the collectivization of all productive property. The concept is ancient, however. Early versions of a community of goods exist in myths that describe the earliest stages of human culture; it was a major issue in ancient Athens, a key component of monasticism and became the basis for much criticism of industrial capitalism.

The word communism later became associated with the teachings of Karl Marx (§12) and his followers and came to refer to an authoritarian political system combined with a centralized economic system run by the state. This form of communism has roots in the earlier idea because the ultimate goal of communism, as seen by Marx, was a society in which goods are distributed to people on the basis of need. The older usage continues to exist in a worldwide communal movement and as a standard by which to criticize both capitalism and Marxian communism.

The idea of communism as collectively owned property first appears in the Western tradition in classical Greece. Plato’s *Republic* contains a notable early defence (see Plato §14). Prior to the invention of the word, major communist theories can be found in some parts of the Christian Bible, in medieval monasticism and in Thomas More’s *Utopia* (1516). In all these cases the basis for collectively owned property is that members of society are freed from the need to devote their time to earning a living or caring for private property so that they can devote themselves to something more important such as the pursuit of knowledge, God or personal fulfilment. The assumption is that the need to provide for oneself or one’s family gets in the way of matters considered more important. For example, Plato advocates abolishing the family in his *Republic* because he fears that family ties will both distract the individual from higher things and tempt people to favour one group (family members) over others (non-family members). In monastic communism, which also abolishes the family, all property is owned by the community and each individual member of the community owns nothing, not even their clothes. Everything is provided by the community for each monk or nun; they are, thereby, freed from the burden of property to devote themselves to God. In More’s *Utopia* all houses and their furnishings are as near identical as possible and, since location cannot be identical, people move from house to house in regular rotation.

Later, secularized versions of communism stressed the equitable (not necessarily equal) distribution of, or at least access to, resources, but the underlying principle is quite similar. Rather than freeing some or even all people in a society to devote themselves to a higher cause, secular communism is designed to allow everyone to pursue personal fulfilment. It may best be characterized by a slogan adopted by Marx that appears to have been first published on the title page of Cabet’s *Voyage en Icarie* (1840): ‘From each according to his ability, to each according to his need’. In other words, each person contributes to society to the best of their ability in the areas of work for which they are suited; in return, society provides their basic needs. The underlying assumption is that all human beings deserve to have their needs met simply because they are human beings; differential ability and talent does not make one person more deserving than another. A specific case is the assumption by most communist theorists that there should be no difference in treatment of those who contribute to society through physical labour and those who contribute through mental labour. For example, in 1888 Edward Bellamy published *Looking Backward*, a utopian novel that became an instant bestseller and produced a worldwide movement. In it, Bellamy advocated an absolutely equal income for all members of society that could then be used by each individual to meet their own felt needs. An approach adopted by many intentional communities is for the group to make collective or social decisions (either by consensus or by majority rule) about economic matters that affect the community as a whole but to provide each individual member of the community with a discretionary income to use as they wish.

Marx maintained major aspects of this approach in the stage of human development that he called 'full' or 'pure' communism or just communism. The non-alienated people of this future communism will create a world in which income will be distributed on the basis of need (see Alienation §§3-4; Marx, K. §4); since everyone will be a productive labourer, there will no longer be any classes; and, because there will no longer be a need for political power to enforce class dominance, the state will gradually disappear to be replaced with decentralized, non-political administrative agencies. Since everyone will work, there will be high productivity and, therefore, plenty for all. Given the changed social situation, people will begin to think differently and social distinctions between occupations and between city and country will disappear. Thus, this form of communism is, in its essentials, identical to the earliest communist tradition. At least one major twentieth-century Marxist theorist, Ernst Bloch (1885-1977) in *Das Prinzip Hoffnung (The Principle of Hope)* (1959) argued that this utopian goal should be at the centre of Marxist theory (see Utopianism §4).

While Marxism and its version of communism predominantly took a different road, the more fundamental and historically earlier theory did not disappear. Non-Marxist forms of collective property have existed and been defended as part of the communal movement best represented by the Israeli kibbutzim and the US communal movement of the early nineteenth and mid-twentieth centuries, and by some forms of anarchism (see Anarchism §3). Communism as common property and as a vision of a better life for all is still a living tradition.

The arguments against communism take a number of different forms. The simplest rely on assumptions about human nature radically at variance with those of communism's proponents. The assumption is made, with little real evidence, that human beings are 'naturally' competitive and that therefore communism cannot work (see Human nature §1). A more developed analysis argues that communism is necessarily economically inefficient and will, therefore, be unable to provide as high a standard of living as a non-communist system. Some go so far as to argue that communism is impossible to sustain over long periods of time because its inefficiency is so great that the economic system must sooner or later collapse. Of course, economic efficiency is very low in the scale of values held by most supporters of traditional communism. Proponents of communism generally take the position that economic efficiency symbolizes the competitive system that they oppose and stands in the way of the cooperative community they hope to achieve.

Today, many believe that the time of communism has passed, largely because Marxist communism has been discredited in much of the world. But communism is not, and never has been, reducible to the Marxist version. Most fundamentally, it is the economic basis for dreams of complete human fulfilment, whether it is sought in monastic orders, intentional communities or whole societies. That dream persists, and with it the ideals of communism.

Community and communitarianism

Reflections on the nature and significance of community have figured prominently in the history of Western ethics and political philosophy, both secular and religious. In ethics and political philosophy the term 'community' refers to a form of connection among individuals that is qualitatively stronger and deeper than a mere association. The concept of a community includes at least two elements: (1) individuals belonging to a community have ends that are in a robust sense common, *not merely congruent private ends, and that are conceived of and valued as common ends by the members of the group; and (2) for the individuals involved, their awareness of themselves as belonging to the group is a significant constituent of their identity, their sense of who they are.*

In the past two decades, an important and influential strand of secular ethical and political thought in the English-speaking countries has emerged under the banner of communitarianism. The term 'communitarianism' is applied to the views of a broad range of contemporary thinkers, including Alasdair MacIntyre, Charles Taylor, Michael Sandel, and sometimes Michael Walzer (MacIntyre 1981; Sandel 1982; Taylor 1979, 1989; Walzer 1983). It is important to note, however, that there is no common creed to which these thinkers all subscribe and that for the most part they avoid the term.

There are two closely related ways to characterize what communitarians have in common; one positive, the other negative. As a positive view, communitarianism is a perspective on ethics and political philosophy that emphasizes the psycho-social and ethical importance of belonging to communities, and which holds that the possibilities for justifying ethical judgments are determined by the fact that ethical reasoning must proceed within the context of a community's traditions and cultural understandings (Bell 1993: 24-45). As a negative view, communitarianism is a variety of anti-liberalism, one that criticizes liberal thought for failing to appreciate the importance of community.

At present the communitarian critique of liberalism is more developed than is communitarianism as a systematic ethical or political philosophy. Existing communitarian literature lacks anything comparable to Rawls' theory of justice or Feinberg's theory of the moral limits of criminal law, both of which are paradigmatic examples of systematic liberal ethical and political theory. For the most part, the positive content of the communitarians' views must be inferred from their criticisms of liberalism. Thus, to a large extent communitarianism so far is chiefly a way of thinking about ethics and political life that stands in fundamental opposition to liberalism. To some, communitarian thinking seems a healthy antidote to what they take to be excessive individualism and obsessive preoccupation with personal autonomy. To others, communitarianism represents a faliure to appreciate the value - and the fragility - of liberal social institutions. The success of communitarianism as an ethical theory depends upon whether an account of ethical reasoning can be developed that emphasizes the importance of social roles and cultural values in the justification of moral judgments without lapsing into an extreme ethical relativism that makes fundamental ethical criticism's of one's own community impossible. The success of communitarianism as a political theory depends upon whether it can be demonstrated that liberal political institutions cannot provide adequate conditions for the flourishing of community or secure appropriate support for persons' identities so far as their identities are determined by their membership in communities.

1 Community

If I am a member of a community, I conceive of the goals and values I share with my fellows as essentially *our* goals and values, not just as goals and values that happen to be the same for all of us because of a contingent convergence of our individual interests. Each member thinks of furthering the community's ends primarily as gains for *us*, not as a gain for themselves that happens to be accompanied by similar gains for other individuals in the group. In the activities that are the life of the community, individuals think of themselves first and foremost as members of the group. Thus, at least in the course of these activities, the distinction between what is in your interest, as opposed to mine or ours, breaks down or recedes into the background.

In contrast, in an association individuals typically conceive of their interests as distinct, even if their goals are collective; that is, as states of affairs that necessarily involve the group. For example, if they are an association rather than a community, when the employees in a firm work together to secure an important contract for the company (the collective goal), each will cooperate with others only to further their own interest, conceiving of it as

distinct from, although congruent with, that of the others.

A contrast can also be drawn between how the members of a community regard the process of pursuing the common goal and how that process is regarded in an association. In a community, the process itself (or rather the relationships among members of the group that constitute the process) is seen by members of the group to be valuable in itself, independently of whether it is effective in achieving the goal of the process. In an association, the relationships that exist in the process of pursuing the collective goal are viewed as being of only instrumental value for attaining private goods for each of the individuals involved.

Since a community is defined at least in large part by a set of shared values and goals, the second element in our analysis of community, shared identity, is at least partly normative. In other words, if in saying who I am I feel it important to identify myself as, for example, a Catholic, then this characterization of who I am is not a description of myself as being a member of a certain religious group; it also includes the awareness that I have certain commitments, an allegiance to certain values and the perception that I have certain obligations by virtue of being a member of this group.

These familiar ways of contrasting communities with mere associations have the virtue of throwing the distinction between the two into bold relief, but they oversimplify. Being a community is a matter of degree: groups fall along a continuum, from communities in the strict sense, in which the sense of a shared identity is fundamental to a person's most basic conception of themselves and in which allegiance to the common interest eclipses any distinct conception of private interest, to mere associations, whose members are connected by the most tenuous and transitory ties of private interests or tastes and whose identity derives chiefly from sources other than membership of the group (Feinberg 1988: 81-122). For example, in many groups, individuals will be motivated to cooperate with others both by a sense of community, according to which what counts is whether 'we' succeed, and by their own private interests in the outcome of the common endeavour, which they will be able to distinguish quite clearly from the interest of the group. Similarly, the extent to which the members will conceive of their membership as being an important component of who they are (what their values and commitments are, and so on) will vary across different groups. Thus the extent to which a group is a community will depend upon how dominant the sense of common, not merely congruent, goals is, and how large a role the sense of allegiance to the values and ends of the group plays in each individual's sense of who they are.

2 Communitarianism

To determine what, according to communitarians, the true significance of participation in community is, we must see the ways in which communitarians believe liberalism has failed to acknowledge that significance.

The first obstacle to reconstructing a positive communitarian view from the communitarian critiques of liberalism is the fact that communitarians have sometimes been unclear about what liberalism is, and in some cases apparently have made uncharitable assumptions about what liberalism is committed to (Feinberg 1988: 86-8; Buchanan 1988: 853-7). One useful place to begin is with a rather narrow but clear articulation of liberalism as a minimal political philosophy - a thesis about the proper role of the state. What I shall call the *liberal normative political thesis* is simply that the state is to place a priority on the enforcement of the basic individual and civil rights, those rights which, roughly speaking, are found in the US Constitution's Bill of Rights and in Rawls' First Principle of Justice, the Greatest Equal Liberty Principle (Rawls 1971: 61) (see Rawls, J. §1). These include the rights to freedom of religion, expression, thought and association, the right of political participation (including the right to vote and to run for office), and the rights of legal due process and equality before the law.

This fundamental thesis of liberal political philosophy implies another: namely, that the proper role of the state is to protect these basic rights, not to make its citizens virtuous or to impose upon them any particular or substantive conception of the good life or of the common good. By honouring this commitment to protect individual and civil political rights and forgoing any other projects that would violate them, the state recognizes a distinction between the private and the public spheres, and hence a limit on its own authority as well as a domain of autonomy for individuals (see Law, limits of §4).

In marking off a private sphere through the protection of individual rights liberalism not only demarcates a domain of autonomy for individuals, it also makes room for a variety of associations - and communities. For this reason it is misleading to say that liberalism protects individual freedom rather than community.

3 Communitarian criticisms of liberalism

The following four criticisms form the core of the communitarian attack on liberalism. Not all are advanced by every thinker usually labelled communitarian.

(1) Liberalism rests on an individualism that is both ontologically and motivationally false. Liberal ontology asserts that only individuals exist and that all putative properties of groups can be reduced to properties of individuals; liberal motivational theory assumes that individuals are motivated solely by preferences for private goods, and that they desire participation in groups only as a means to achieving such goods.
(2) Liberalism undervalues political life, viewing participation in the political community as a mere instrumental good, valuable only as a means toward the attainment of the various private ends that individuals have, rather than as something valuable in itself.
(3) Liberalism presupposes a defective conception of the self, not recognizing that the self is ‘embedded’ in and partly constituted by communal commitments that are not objects of choice. Thus liberalism fails to understand that what one’s obligations are is determined, to a large extent, by one’s identity as a member of the community and the roles one occupies within the community (see Obligation, political §2).
(4) The liberal emphasis on individual rights devalues, neglects, and ultimately undermines community; yet participation in community is a fundamental and irreplaceable ingredient in the good life for human beings.

Only the fourth communitarian criticism is a direct attack on the liberal normative political thesis. The other three are instances of a characteristic communitarian move, one which is most explicit perhaps in Sandel and Taylor: namely, that of attempting to undermine the liberal normative political thesis by exposing flaws in the system of beliefs upon which it supposedly rests. As we shall see, one problem with this strategy is the tendency on the part of those who employ it to fail to appreciate the range of different considerations that the liberal can invoke to support the liberal normative political thesis. At most, only some of these justifications may include beliefs which communitarianism shows to be false. Other justifications for liberalism - including what appear to be the most plausible - may remain intact.

The first criticism is easily rebutted. The liberal normative political thesis does rest on an individualistic premise, but the premise is neither the ontological individualism nor the motivational individualism which communitarians rightly have attacked. Liberalism is individualistic only in a *moral* sense. Liberals hold that what matters ultimately, morally speaking, is individuals - their autonomy and wellbeing.

Moral individualism does not commit the liberal to ontological individualism: holding that individuals are morally primary does not commit one to denying that groups exist or that they are reducible without remainder to the properties of individuals. Similarly, liberalism can readily admit that in order to describe the interest that individuals have in participating in groups it is necessary to make reference to institutions and practices. Liberals can also agree that the institutional or social concepts used to describe the interests that individuals have in belonging to groups and pursuing shared ends are not reducible to pre-institutional or pre-social concepts (such as that of the ‘atomistic’ individual existing in a state of nature). Liberalism, as a normative political thesis about the priority of the basic civil and political rights (and the proper role of the state and the limits of its authority), does not entail any such individualistic views; nor do the more plausible lines of justification invoked to support the liberal normative political thesis include such views among their premises. The latter justifications are simply attempts to show how a political order that protects the basic civil and political rights, and hence has a rather limited role for the state and a large private sphere in which diverse individuals (and groups) can flourish, will, in the long run, and in the majority of cases, best serve the autonomy and welfare of individuals.

The second communitarian criticism, that liberalism undervalues participation in the political community, is harder to assess. Those who voice it sometimes neglect to distinguish clearly between two quite different theses. The first is that participation in the political community is valuable in itself, as a significant ingredient in the good life for all or most human beings. Liberalism need not, and does not, deny this. The second is that the good life requires that one participate in what may be called an all-inclusive political community or in some rather direct and substantial way in the highest-level political organization in one’s society.

The first thesis is more controversial than the bare claim that participation in some form of community or other is

an essential ingredient in the good life. It is the claim that participation in *political* community is essential. Although clearly in need of systematic defence, the latter claim is not implausible. It can be supported by arguing, as Aristotle seems to have done, that the good life for human beings, or at least the best life, requires the exercise and development of certain powers of will and intellect that can only be achieved through participation in activities in which one rules and is ruled in turn (see Aristotle).

Notice, however, that even if this first thesis is granted, we are still a great distance from the second. For one may be able to achieve the good of participation in political community without participating in any significant way in an overarching political community, or the highest level of political organization. All that is necessary is that one participate in one or more political subcommunities, which might include not only local governments but also many other types of communities, religious and secular, in so far as they include a substantial political dimension in their internal activities.

Given the apparent diversity of the conditions of human flourishing, the sweeping pronouncement that the good life or even the best life for all (or even most) human beings requires significant participation in the most inclusive form or highest level of political organization appears rather dogmatic. To my knowledge no communitarian has shouldered the burden of supporting this second thesis.

The third communitarian criticism is sometimes formulated as the slogan that liberalism - at least the liberalism of theorists such as John Rawls and Ronald Dworkin - conceives of ‘the self as being given prior to its ends’ (Sandel 1984a: 115). Put more positively, this is the thesis that an individual’s identity is to a significant degree constituted by an allegiance to the ends to which they are committed by virtue of their membership of the community, and more specifically by the roles they occupy in it.

Liberals need not and should not deny that when human beings become aware of themselves as moral agents and when they confront questions about what they ought to do, they already recognize themselves as having an identity. Nor should they fail to acknowledge that this identity is constituted to a large extent by the various roles in which they find themselves in the practices of their community (or communities), and that these roles carry with them certain obligations and commitments. Liberalism need not deny this commonsensical truth, which we may call ‘the fact of embeddedness’. There is, however, a more radical interpretation of the thesis that which liberal thinkers do not espouse - but one which appears to be quite implausible. This is the view that the ends that are ‘given’ as part of a person’s socially generated identity are *incorrigible* for that individual, that they cannot meaningfully be objects of criticism by the individual, and hence that they can neither be chosen or rejected by them.

It would be uncharitable to say that communitarians unequivocally hold this more radical interpretation of the embeddedness thesis, but there are passages in their writings that suggest that they do:

> I can only answer the question ‘What am I to do?’ if I can answer the prior question ‘Of what story or stories do I find myself a part’? We enter human society, that is, with one or more imputed characters - roles into which we have been drafted.… I am someone’s son or daughter, someone else’s cousin or uncle; I am a citizen of this or that city, a member of this or that guild or profession; I belong to this or that clan, that tribe, this nation. Hence what is good for me has to be the good for one who inhabits these roles. As such I inherit from the past of my family, my city, my tribe, my nation, a variety of debts, inheritances, rightful expectations, and obligations.
>
> (MacIntyre 1981: 203-5)

If the point is that the self is embedded in the sense that the obligations a person has are given, *irrevocably so*, by their membership of and particular role within a community, that the obligations that are imputed along with membership and roles are not subject to criticism, and that a person cannot rationally choose to reject such roles, then liberalism does deny the embeddedness of the self. For liberalism, to the extent that it emphasizes individual autonomy, stresses the ability of individuals, at least under favourable conditions in which social practices and institutions allow the free flow of information and untrammelled discussion, to exercise critical judgment about the suitability of their roles and the validity of the values of their communities, and hence to question the obligations that are imputed to them.

To put the same point in terms of what may be called the normative significance of identity, communitarians

sometimes appear to hold that an individual cannot critically assess those putative obligations that are constitutive of their identity. On the face of it, however, this seems quite wrong. The fact that I am a racist - that racism is partly constitutive of my identity - does not show that I am obliged to treat white people as if they were superior to black people, nor that it is impossible for me to criticize my racist beliefs and reconstitute my identity as that of one who is dedicated to racial equality. It makes perfectly good sense to say that I ought to disavow my racist identity and strive to construct a new, nonracist identity.

The communitarian might reply that even when criticism of culturally-imputed obligations and values does occur, it must always proceed by drawing on conceptual, factual and moral resources that are themselves available only through the culture in question. This may in fact be what MacIntyre has in mind when, immediately following the passage cited above, he states that the obligations one inherits from one's social roles are one's moral starting point. The implication is that one may not remain at this starting point. One may come to revise one's conception of what is valuable, what one's obligations are, and so on - but only by utilizing tools of criticism that are also given by one's community.

On this interpretation, the embeddedness thesis is the claim that if an individual is able to exercise critical judgment about whether to act on the values and perceived obligations that are imputed to them by their community, this is only possible by drawing on perspectives that are available within the very communal normative structure that imputes the values in the first place.

If this means that all factual assumptions, concepts and moral principles that an individual relies on to criticize the values of his own community must be wholly endogenous to that community, must originate there or must be widely accepted there, then it not only appears to be false, but would seem to rest upon a view of communities which, ironically, is 'atomistic individualism' writ large. On this view, communities and the systems of values they embody are like the self-contained, *sui generis* and impermeable 'bare individuals' which communitarians believe to people the illusory world of liberal theory. But surely it cannot be denied that communities interact and that they borrow from one another's cultures, any more than it can be denied that the values of individuals are shaped by the social forces within which they develop.

In fact, modern societies are characterized by not only a plurality of interpenetrating communal cultures within the boundaries of a given society, but also by increasing interaction among different societies as the global economy and the global culture it brings with it expand. For example, Western principles concerning human rights in general and the equality of women in particular have been used, with some success, to criticize the assigned roles and perceived values and obligations of non-Western societies. Once it is recognized that criticism of acculturated values sometimes relies at least in part on beliefs, concepts or principles that originate outside the culture, then even the more moderate version of the embeddedness thesis is seen to be implausible.

Nevertheless an important truth remains: even if one is able to criticize obligations that are constitutive of one's culturally-assigned identity, all reasoning about what one ought to do must begin with a recognition of who one is and what one's obligations are as determined by one's identity. If this is what is meant by embeddedness, then communitarians have articulated an important truth about the nature of ethical reasoning and critical ethical reflection - one which liberal thinkers have perhaps generally neglected. What is not clear, however, is how taking this fact of embeddedness seriously affects the conclusions about the state and individual rights which liberalism seeks to defend.

The fourth and final communitarian criticism of liberalism is potentially more telling. The claim is that liberalism exalts individual autonomy to the neglect and detriment of community. The communitarians' point, presumably, is both that: (1) the justifications liberals offer to support the normative political thesis concerning the priority of basic individual, civil and political rights rest on an excessively positive valuation of individual choice or autonomy; and that (2) implementing the liberal priority on these individual rights is damaging to communities.

Contemporary liberals have offered strong arguments against both elements of the communitarian attack. First, liberal theorists can and do explicitly recognize the importance of community, and to that extent do not assume that individual autonomy is the sole value to be protected. Some of the most prominent contemporary liberal theorists, including Rawls, Dworkin and Feinberg, are most naturally read as ascribing to a moral individualism that bases the case for individual rights ultimately on both the autonomy and the wellbeing of individuals

(Buchanan 1988: 878-81). If this is the case, then all that is needed to incorporate a fundamental appreciation for community into the heart of the liberal justification for individual rights is the commonsensical thesis: for all or most human beings, participation in communities is an important ingredient in their wellbeing, as something that is intrinsically valuable. Once again, there is nothing in liberal theory, or at least in its more plausible variants, that precludes a recognition of the truth of this thesis.

Some contemporary liberal thinkers have argued that participation in community is also valuable because the community's shared values provide a context for meaningful choice (Kymlicka 1989: 205-19). To the extent that this is so, the opportunity to participate in flourishing communities is valuable not only from the perspective of individual wellbeing but also from that of individual autonomy, since autonomy can flourish only where meaningful choices are possible.

Liberalism, therefore, can include a proper recognition of the importance of participation in communities for individuals and can avoid an exclusive emphasis on individual autonomy that would neglect the importance of community for individual wellbeing. In addition, a number of liberal thinkers have pointed out that liberalism's priority on individual civil and political rights not only provides scope for individual autonomy but also serves to protect communities and to allow them to flourish (Feinberg 1988: 108-12; Buchanan 1994: 11-15).

To understand how individual rights protect communities, consider the rights to freedom of association, expression and religion. Historically these rights, as well as political participation rights and legal due process rights, have provided a strong bulwark against attempts by the state or rival communities to destroy or dominate minority communities. They allow individuals to partake of the essential good of community, and to enjoy the context for meaningful choice that community values provide, both by protecting existing communities from interference and by giving individuals the freedom to unite with like-minded others to form new communities. It is wrong to assume, then, that because the rights which liberals champion are individual rights, the purposes those rights serve and the values upon which they rest are purely individualistic.

This is not to say, of course, that any existing liberal theory provides a fully satisfactory way of accommodating both the importance of individual autonomy and the importance of participation in community. Nor is it to suggest that the particular understandings of the scope and limits of individual rights that liberals typically advocate successfully resolve all conflicts between the interests of individuals *qua* individuals and the interests of communities. Perhaps the most obvious instances of such unresolved conflicts - and of the challenge to liberalism that they represent - lie in the area of tensions between the interest in preserving a community's longstanding culture (or certain central features of it) and the liberal commitment to ensuring that children are educated so as to be able to make their own choices as to how to live. For example, some religious communities in the USA and elsewhere have sought an exemption from public schooling requirements on the grounds that exposure to ideas and values dominant in the majority culture would weaken their own community's traditions. Here there seems to be a direct conflict between liberalism's emphasis on individual autonomy and freedom of expression, and the value of preserving a community. And to say, as I have done, that liberalism ought to and can recognize the importance of participation in community for the wellbeing and autonomy of individuals does not in itself shed any light on how the balance should be struck between the individual rights liberalism has traditionally championed and the need to protect cultures when the former and the latter are in conflict.

If striking an adequate balance requires rejecting what I have taken to be the core of liberalism - the normative political thesis of the priority of individual rights - then the fourth major communitarian criticism of liberalism will be telling: the liberal priority on individual rights will be seen to rest on an inadequate appreciation of the value of community. If this is the case, then perhaps the most fruitful line of development for communitarian thought would be a concerted effort to show how political systems that only recognize individual rights as basic fail to respond satisfactorily to the need to preserve communities.

One important element of this line of inquiry is the question of whether states should recognize *group* rights that are justified according to the protection they provide for communities or their cultural values and that are basic rights in the sense of not being generated through the exercise of the individual rights which liberalism recognizes, such as the right to freedom of association and the legal right to make contracts. (Examples of basic group rights - those not generated through the exercise of individual rights - might include language rights for national minorities and collective land rights for indigenous peoples). If the liberal thesis of the primacy of individual rights rules out

recognition of any basic group rights, then a successful case for basic group rights (as needed to provide sufficient protection for communities) would be a conclusive communitarian objection to liberalism thus interpreted. As a way of developing systematically communitarianism both as a positive view and as a critique of liberalism, this line of research may prove crucial (see Multiculturalism).

4 Conclusions

If communitarianism is understood as being, or as centrally including, a radical critique of liberalism, where the latter is construed narrowly as the normative political thesis that the proper role of the state is to uphold the basic individual civil and political rights, then the communitarian project has thus far proven inconclusive. For liberalism can, and a growing number of contemporary liberal thinkers do, take the value of participation in community seriously - thus acknowledging the central tenets of communitarianism while denying that liberalism cannot incorporate them. However, if liberalism is understood to exclude entirely any role for basic group rights in the protection of cultural communities, then the communitarian critique of liberalism may well turn out to be telling.

Alternately, communitarianism might be viewed more positively, not primarily as a criticism of the liberal normative political thesis but as a rationale for an expanded and enriched research agenda in ethics and political philosophy. Taking the importance of community seriously in political philosophy would mean acknowledging and attempting to resolve systematically the conflicts that can arise in any theory that recognizes the importance of both individual autonomy and participation in communities. And doing so may require rethinking the scope and limits of theories of individual rights and a willingness to entertain the possibility that these rights must be supplemented with special group rights designed to provide added protection to especially vulnerable communities (Buchanan 1994: 11-15).

In ethical theory the communitarian message is to take seriously the fact that to a large extent moral obligations are the product of explicit choices or voluntary agreements made not by autonomous individuals operating in a social and institutional vacuum, but by individuals who regard themselves and are regarded by others as members of communities, as occupants of particular social roles. In addition, communitarianism stresses a fundamental truth about how ethical reflection and argumentation must begin; namely, in the concrete context of social practices in which individuals find themselves and in an awareness that the sense of self and the recognition of moral values are inextricably bound together. Thus, another important item on the agenda for a communitarian ethical theory is a careful articulation of the extent to which the social starting place that supplies one's identity places unsurpassable limitations on the sorts of moral conclusions one can draw and the kinds of moral commitments one can come to make through a process of rational reflection.

Complexity, computational

The theory of computational complexity is concerned with estimating the resources a computer needs to solve a given problem. The basic resources are time (number of steps executed) and space (amount of memory used). There are problems in logic, algebra and combinatorial games that are solvable in principle by a computer, but computationally intractable because the resources required by relatively small instances are practically infeasible.

The theory of $\mathcal{NP}$-completeness concerns a common type of problem in which a solution is easy to check but may be hard to find. Such problems belong to the class $\mathcal{NP}$; the hardest ones of this type are the $\mathcal{NP}$-complete problems. The problem of determining whether a formula of propositional logic is satisfiable or not is $\mathcal{NP}$-complete. The class of problems with feasible solutions is commonly identified with the class $\mathcal{P}$ of problems solvable in polynomial time. Assuming this identification, the conjecture that some $\mathcal{NP}$ problems require infeasibly long times for their solution is equivalent to the conjecture that $\mathcal{P} \neq \mathcal{NP}$. Although the conjecture remains open, it is widely believed that $\mathcal{NP}$-complete problems are computationally intractable.

1 Time and space in computation

The theory of complexity analyses the computational resources necessary to solve a problem. The most important of these resources are *time* (number of steps in a computation) and *space* (memory capacity of the computer). This entry is mainly concerned with the complexity of decision problems having infinitely many instances. There is another approach to complexity applicable to individual finite objects, in which the complexity of an object is measured by the size of the shortest programme that produces a description of it (see Computability and information).

The model for computation chosen here is the Turing machine (see Turing machines). The *time* for a computation is the number of steps taken before the machine halts; the *space* is the number of cells of the tape visited by the reading head during the computation. Several other models of sequential computation have been proposed. The time and space complexity of a problem clearly depend on the machine model adopted. However, the basic concepts of complexity theory defined in this entry are robust in the sense that they coincide for any reasonable model of sequential computation.

Let Σ be a finite alphabet, and Σ^* the set of all finite strings in this alphabet. A subset of Σ^* is said to be a ‘problem’. The size $|s|$ of a string *s* is its length, that is, the number of occurrences of symbols in it. A function *f* defined on Σ^* and having strings as its values is computed by a Turing machine *M* if for any string *s* in Σ^*, if *M* is started with *s* on its tape, then it halts with $f(s)$ on its tape. A problem *L* is solvable if there is a Turing machine that computes the characteristic function of *L* (the function *f* such that $f(s) = 1$ if *s* is in *L* and $f(s) = 0$ otherwise). For example, the problem Satisfiability of determining whether a formula of propositional logic is satisfiable or not is solvable by the familiar method of truth tables.

Solvable problems can be classified according to the time and space required for their solution. If *f* is a computable function, then we say that *f* is computable in time $T(n)$ if there is a Turing machine *M* computing *f* and a constant *c* such that for any input *s*, *M* halts with output $f(s)$ in at most $c \cdot T(|s|)$ steps. A function *f* is computable in space $S(n)$ if there is a machine *M* computing *f* and a constant *c* such that for any input *s*, *M* halts after visiting at most $c \cdot S(|s|)$ squares on its tape. A problem *L* is solvable in time $T(n)$ if the characteristic function of *L* is computable in time $T(n)$; *L* is solvable in space $S(n)$ if the characteristic function of *L* is computable in space $S(n)$. For example, the truth table method shows that Satisfiability can be solved in time 2^n and space *n* (we need only enough tape space to evaluate the truth table one row at a time).

One of the most significant complexity classes is the class $\mathcal{P}$ of problems solvable in polynomial time. A function is polynomial-time computable if there exists a *k* for which *f* is computable in time n^k. A problem is solvable in polynomial time if its characteristic function is polynomial-time computable. The importance of this class rests on the widely accepted working hypothesis that the class of practically feasible algorithms can be identified with those algorithms that operate in polynomial time. Similarly, the class $\mathcal{PSPACE}$ contains those problems solvable in polynomial space. The class $\mathcal{EXPTIME}$ consists of the problems solvable in exponential time; a problem is

solvable in exponential time if there is a *k* for which it is solvable in time 2^{n^k}. The class $\mathcal{EXPSPACE}$ contains those problems solvable in exponential space. The problem Satisfiability is in $\mathcal{EXPTIME}$; whether it is in $\mathcal{P}$ is a major open problem.

2 Hierarchies and reductions

The complexity classes defined above represent only a few levels within detailed hierarchies defined by space and time bounds. To state results on the hierarchies, we define a class of functions that includes all the complexity bounds considered here. A function $S(n)$ is said to be fully space constructible if there is a Turing machine that uses exactly $S(n)$ tape cells for any input of length *n*. With this definition we can state the space hierarchy theorem (Hartmanis, Lewis and Stearns 1965):

If $S_1(n)$ and $S_2(n)$ are fully space constructible functions and if

$\liminf_{n\to\infty} \frac{S_1(n)}{S_2(n)} = 0,$

then there exists a problem solvable in space $S_2(n)$ but not in space $S_1(n)$.

In informal terms, the theorem says that if $S_1(n)$ and $S_2(n)$ are 'reasonable' mathematical functions and asymptotically $S_2(n)$ grows faster than $S_1(n)$, then there is a problem solvable in space $S_2(n)$ but not in $S_1(n)$. For example, there is a problem solvable in space n^3, but not in space n^2. A similar but slightly weaker time hierarchy theorem can be proved for complexity classes defined by time bounds.

The problems in these theorems that separate the complexity classes are defined by diagonalization. Applications of the theorems to naturally occurring problems in logic and mathematics are obtained by using the tool of efficient reductions. These are the complexity-theoretic analogue of the notion of Turing reducibility in recursion theory.

Let L_1 and L_2 be problems expressed in alphabets Σ_1 and Σ_2, respectively. L_1 is said to be polynomial-time reducible to L_2 (briefly, reducible to L_2) if there is a polynomial-time computable function *f* from Σ_1^* to Σ_2^* such that for any *s* in Σ_1^*, $s \in L_1$ if and only if $f(s) \in L_2$. Many other notions of reducibility have been considered. The important property of polynomial-time reducibility is that it is compatible with the main complexity classes $\mathcal{C}$ considered in this entry; this means that if L_2 is in a complexity class $\mathcal{C}$ and L_1 is reducible to L_2, then L_1 is also in $\mathcal{C}$.

3 Provably intractable problems

If $\mathcal{C}$ is a complexity class and *L* is a problem in $\mathcal{C}$ such that any problem in $\mathcal{C}$ is reducible to *L*, then *L* is said to be $\mathcal{C}$-complete. Such problems are the hardest problems in $\mathcal{C}$; if any problem in $\mathcal{C}$ is computationally intractable, then a $\mathcal{C}$-complete problem is intractable.

The time hierarchy theorem implies that there are problems in $\mathcal{EXPTIME}$ requiring exponential time for their solution, no matter what algorithm is employed. It follows that the same is true for any problem that is $\mathcal{EXPTIME}$-complete. Such problems can be shown to exist in the area of combinatorial games. For example, we can define generalized chess to be a game similar to standard chess, but played on an $n \times n$ board. The problem of determining of an arbitrary position in generalized chess whether or not the first player has a winning move is $\mathcal{EXPTIME}$-complete (Fraenkel and Lichtenstein 1981). If *M* is a Turing machine that solves this problem, there is a constant $c > 1$ such that infinitely many $n \times n$ chess positions exist for which *M* requires time greater than c^n to determine whether the first player has a win or not. In this sense, chess can be said to be a provably difficult game.

Problems that are $\mathcal{EXPSPACE}$-complete are also inherently intractable. In algebra, the word problem for commutative semigroups has been proved $\mathcal{EXPSPACE}$-complete (Mayr and Meyer 1982). An instance of this problem is a finite sequence of equations of the form $s = t$ where the terms *s* and *t* are constructed from a set of constants using a single binary operation; the problem to be solved is whether or not the last equation in the sequence can be inferred from the earlier equations by the usual rules for equations, assuming the commutative and associative laws for the operation. It follows that any Turing machine solving this problem requires an exponential amount of space for infinitely many inputs.

Logical theories are a source of solvable decision problems for which no feasible algorithm exists. An example is first-order arithmetic, restricted to addition. The language of this theory is a first-order language based on identity, the addition symbol and the constants 0 and 1. The decision problem consists in determining whether or not a sentence in this language is true in the natural numbers. Presburger in 1930 showed that this problem is decidable by the method of eliminating quantifiers. In 1973 Rabin and Fischer showed that the complexity of the problem is doubly exponential. This means that for any machine solving this problem, there is a constant $c > 0$ such that for infinitely many sentences of length *n* the machine takes at least $2^{2^{cn}}$ steps to determine whether it is true or not.

Still more powerful lower bounds can be proved by allowing second-order quantifiers. The weakest such extension allows quantifiers ranging over finite sets. Let WS1S be the weak monadic second-order theory of one successor. This theory is formulated in a second-order language with equality, based on the constant 0 and the successor function. The decision problem consists of deciding whether a sentence of WS1S is true in the natural numbers when the second-order quantifiers range over finite sets of natural numbers. It was shown decidable by Büchi in 1960. Define a function $F(n, m)$ by the recursion

$$F(n, 1) = 2^n$$
$$F(n, m+1) = 2^{F(n,m)} .$$

If *d* is a real number greater than 0, then $f(d, n) = F(n, [dn])$ represents exponentiation by a stack of $[dn]$ 2's, where $[x]$ is the integer part of *x*. Albert Meyer in 1972 showed that an algorithm deciding WS1S must use space $f(d, n)$ infinitely often for some $d > 0$. This result shows that the decidability of WS1S is of a purely theoretical nature, so that the theory may be considered undecidable from a practical point of view.

The conclusion of the previous paragraph could be challenged by pointing out that Meyer's lower bound is an asymptotic result that does not rule out a practical decision procedure for sentences of practically feasible size. However, a further result shows that astronomical lower bounds can be proved for WS1S even if we restrict the length of sentences. A Boolean network or circuit is an acyclic directed graph in which each node is labelled with a variable of one of the logical operators 'and', 'not'. The nodes labelled with a variable have no incoming edges, while those labelled 'and' have two, and those labelled 'not' have one. There is exactly one node (the output node) with no outgoing edge. A circuit computes a Boolean function (truth-function) of the variables labelling its input nodes in an obvious way. Meyer and Stockmeyer showed that any such network that decides the truth of all sentences of WS1S of length 616 or less (encoded as binary strings) must contain at least 10^{123} nodes. Even if the nodes were the size of a proton and connected by infinitely thin wires, the network would densely fill the known universe.

4 $\mathcal{NP}$ and the polynomial-time hierarchy

A very common type of practical computational problem takes the form of searching for a solution to a set of conditions, where a proposed solution can be checked easily for correctness. Problems of this kind appear naturally in fields such as operations research, automated theorem proving, computer algebra, linear programming, graph theory and many other areas of discrete mathematics. The features common to such problems have been formalized in the theory of $\mathcal{NP}$-completeness.

A *k*-place relation holding between finite strings of symbols in a finite alphabet Σ is said to be polynomial-time computable (see §1 above) if its characteristic function is polynomial-time computable. (The characteristic function of a relation *R* is the function *f* such that $f(\langle s_1, \ldots, s_k \rangle) = 1$ if $R(s_1, \ldots, s_k)$, and $f(\langle s_1, \ldots, s_k \rangle) = 0$ otherwise.) Let *L* be a problem expressed in an alphabet Σ. *L* belongs to the class $\mathcal{NP}$ if there is a polynomial-time computable relation *R* and a polynomial $p(x)$ such that for any *s* in Σ^*, *s* is in *L* if and only if there exists a *y* such that $|y| \leq p(|s|)$ and $R(s, y)$.

The abbreviation '$\mathcal{NP}$' stands for 'non-deterministic polynomial-time', and is derived from an alternative definition of the class using non-deterministic Turing machines. The instructions for such a machine give for each pair consisting of a scanned symbol and the current state a finite set of permissible actions. A language is in $\mathcal{NP}$ if and only if it is accepted by a non-deterministic Turing machine the length of whose computations is bounded by a polynomial in the size of the input. (A string is accepted by such a machine if there is a computation consisting of permissible actions at each step that ends in an accepting configuration.)

Informally, we could describe the relation between $\mathcal{P}$ and $\mathcal{NP}$ as follows. The class $\mathcal{P}$ consists of problems with a feasible decision method; the class $\mathcal{NP}$ consists of problems where we can guess a solution, and check in a feasible amount of time if our guess was correct.

The problem Satisfiability belongs to $\mathcal{NP}$ since we can take the relation $R(s, y)$ to be the relation '*y* is a truth-value assignment that satisfies the formula *s*'. Satisfiability occupies a central position in the theory of $\mathcal{NP}$-completeness as perhaps the simplest and most natural example of an $\mathcal{NP}$-complete problem. Cook's theorem of 1971 showing that Satisfiability is $\mathcal{NP}$-complete led to the identification of hundreds of $\mathcal{NP}$-complete problems in computer science and discrete mathematics. The book by Garey and Johnson (1979) includes a partial list of such problems.

If a problem is $\mathcal{NP}$-complete, then a polynomial-time algorithm for the problem would lead to a polynomial-time algorithm for any problem in $\mathcal{NP}$ so that the equation $\mathcal{P} = \mathcal{NP}$ would be true. A polynomial-time algorithm for the satisfiability problem for propositional logic would lead to polynomial-time algorithms for hundreds of important problems in discrete mathematics; this follows immediately from the definition of $\mathcal{NP}$-completeness. Because such algorithms have been sought in vain for several decades, it is commonly conjectured that none exists, although no proof of this conjecture has been found. The problem '$\mathcal{P} = \mathcal{NP}$?' is widely considered the most important open problem in theoretical computer science.

The recursive sets can be identified with the computable sets; if we accept the identification of 'feasibly computable' with 'polynomial-time computable' then $\mathcal{P}$ is the class of problems with feasible solutions. The recursively enumerable sets are obtained from recursive relations by unbounded quantification; similarly, the problems in $\mathcal{NP}$ are obtained from relations in $\mathcal{P}$ by polynomially bounded quantification. Thus the class $\mathcal{NP}$ is the complexity-theoretic analogue of the class of recursively enumerable sets, and the $\mathcal{NP}$-complete problems correspond to problems of the highest degree of unsolvability among recursively enumerable sets, such as the halting problem (see Computability theory §5; Turing machines §3).

The analogy with recursion theory has been extended by defining a complexity-theoretic analogue of the Kleene arithmetical hierarchy of recursion theory. The class Σ_k^p is defined as the class of problems expressible in the form

$$\{s\colon (\exists y_1, |y_1| \leq p(|s|))(\forall y_2, |y_2| \leq p(|s|)) \\ \ldots R(s, y_1, \ldots, y_k)\},$$

where there are *k* alternating bounded quantifiers in the prefix of the defining formula, $p(x)$ is a polynomial and *R* is a polynomial-time computable relation. In particular, $\mathcal{NP} = \Sigma_1^p$. The class Π_k^p is given by a definition dual to that for Σ_k^p, where bounded existential quantifiers are replaced by bounded universal quantifiers, and universal by existential.

It is conjectured that all the classes in the polynomial hierarchy are distinct, but no proof is known. If $\mathcal{P} = \mathcal{NP}$, then all the classes in the hierarchy collapse to $\mathcal{P}$. All of the classes in the polynomial hierarchy are contained in $\mathcal{PSPACE}$. The equality $\mathcal{P} = \mathcal{PSPACE}$ is consistent with current knowledge, even though $\mathcal{PSPACE}$ appears to be a much more extensive class than $\mathcal{P}$.

The space and hierarchy theorems above were proved by diagonal arguments similar to those used to prove Church's theorem (see Church's theorem and the decision problem). There are reasons to think that diagonalization cannot be used to separate $\mathcal{P}$ and $\mathcal{NP}$ or other low-level complexity classes (the analogy with recursion theory breaks down at this point). These reasons are based on results about oracle machines. If *A* is a set of strings then a Turing machine with oracle *A* is defined to be a Turing machine that in addition to the normal type of instruction also has instructions of the form (q_i, σ, q_j, q_k), where q_i, q_j, q_k are machine states and σ is a symbol from the tape alphabet (see Turing machines §3). The instruction is interpreted by the machine as follows: when the current state is q_i and the string of symbols to the right of the reading head (starting with the current symbol σ) is in *A*, then the machine's next state is q_j, otherwise its next state is q_k. Thus a Turing machine with oracle *A* has the ability to answer in a single step questions of the type 'Is this string in the set *A*?'. Time and space of a computation by an oracle machine is computed just as for an ordinary Turing machine, counting the time taken for the answer to the oracle query as one step (the oracle answers any query instantaneously).

If *A* is any set of strings, then by imitating the definitions of the complexity classes above, but substituting 'Turing

machine with oracle *A*' everywhere for 'Turing machine' we can define relativized complexity classes $\mathcal{P}^A$, $\mathcal{NP}^A$ and so on. Then we have the following theorem (Baker, Gill and Solovay 1975):

There is a recursive oracle *A* for which $\mathcal{P}^A = \mathcal{NP}^A$ and a recursive oracle *B* for which $\mathcal{P}^B \neq \mathcal{NP}^B$.

The significance of this theorem lies in the fact that known techniques of diagonalization, such as are used in recursion theory, relativize in the presence of oracles. Thus it provides evidence that standard diagonal techniques are inadequate to settle such questions as '$\mathcal{P} = \mathcal{NP}$?'.

Compositionality

A language is compositional if the meaning of each of its complex expressions (for example, 'black dog') is determined entirely by the meanings its parts ('black', 'dog') and its syntax. Principles of compositionality provide precise statements of this idea. A compositional semantics for a language is a (finite) theory which explains how semantically important properties such as truth-conditions are determined by the meanings of parts and syntax. Supposing English to have a compositional semantics helps explain how finite creatures like ourselves have the ability to understand English's infinitely many sentences. Whether human languages are in fact compositional, however, is quite controversial.

It is often supposed that meaning, within a context of use, determines truth-value. Meaning and context are also generally thought to determine what terms refer to, and what predicates are true of - that is, to determine extensions. Because of this, compositionality is generally taken to license a principle of substitutivity: if expressions have the same meaning, and substituting one for another in a sentence does not change the sentence's syntax, the substitution can have no effect on truth. Given this, the idea that meaning is compositionally determined constrains what can be identified with meaning. For example, expressions with the same extension cannot always be substituted for one another without change of truth-value (see Propositional attitude statements §2; Modal logic, philosophical issues in §3).

Natural languages obey a principle of compositionality (PC) only if something more 'fine-grained' than extensions plays the role of meanings, so that expressions with the same extension can still have different meanings. Some say that no matter how fine-grained we make meaning, there will be counterexamples to the claim that meaning is compositionally determined. For example, 'woodchuck' and 'groundhog' are synonymous. But the sentences 'Mae thinks Woody is a woodchuck' and 'Mae thinks Woody is a groundhog' apparently may diverge in truth-value. (Certainly Mae may assert, with understanding, that Woody is a woodchuck, while denying, with understanding, that Woody is a groundhog. For she can understand 'woodchuck' and 'groundhog' but not realize that they are synonymous.) Such arguments lead to the conclusion that meaning is not compositionally determined (or that different forms cannot share meanings).

There is no consensus about such arguments. All agree PCs need *some* restrictions - they do not, for instance, apply to words in quotational constructions. So if 'thinks' is implicitly quotational, the argument loses its force (see Use/mention distinction and quotation). If 'thinks', as Frege held, produces a (more or less) systematic shift in the semantic properties of the expressions in its scope, this perhaps reduces the threat to compositionality (see Sense and reference §§4, 5). Some find such accounts of 'thinks' incredible (Davidson 1984).

Linguists often understand the claim that a language is compositional as asserting an extremely tight correspondence between its syntax and semantics (see Syntax). A (simplified) version of such a claim is that (after disambiguating simple word forms), there is, for each (simple) word, a meaning and, for each syntactic rule used in sentence construction, an operation on meanings, such that the meaning of any sentence is mechanically determined by applying the operations on meanings (given by the rules used in constructing the sentence) to the meanings of the simple parts. (Often a host of extra restrictions are incorporated. For example: the operations may be limited to applying function to argument; the order in which operations are applied may be settled by the structure of the sentence.) Some see such principles as providing significant constraints on semantical theories, constraints which may help us decide between theories which are in other respects equivalent (for example, Montague 1974).

Such strong PCs imply that every ambiguous sentence is either syntactically ambiguous or contains simple expressions which are themselves ambiguous (see Ambiguity). There are putative counterexamples to this. For instance, it has been alleged that 'The women lifted the piano' has two meanings, a 'collective' one (the group lifted it) and a 'distributive' one (each individual lifted it) (see Pelletier 1994).

Context sensitivity makes the formulation of PCs a delicate matter. In some important sense, differing uses of 'that is dead' have like meanings and syntax. But obviously they may differ in truth; presumably such differences may arise even within one context. How can this be reconciled with compositionality?

We might (implausibly) say that demonstrative word forms, strictly speaking, lack meanings (only tokens have such). An alternative (see Kaplan 1989) sees the meaning of the word type ‘that’ as ‘incomplete’, needing contextual supplementation to determine a meaning of the sort other terms have. A third strategy insists that if ‘that is dead but that is not’ is true, its ‘that’s are different demonstrative word types. (Advocates of this view are good at seeing very small subscripts.) This view makes it generally opaque to speakers whether tokens are tokens of the same word type, and thus opaque whether their arguments are logically valid. A fourth strategy sees context as providing an assignment of referents to *uses* of a type in a context. On most ways of working this out, it seems there is no true fleshing out of the principle: the meaning of a sentence type (a) is determined by the meanings of parts and syntax, and (b) determines, in context, the sentence’s truth-value. This approach also seems to undermine the idea that an argument like *that is dead; so that is dead* is formally valid (see Demonstratives and indexicals).

Even if relatively tight PCs should prove untenable (as claims about natural languages), it would not follow that natural languages did not have compositional semantics - finite theories which assign truth-conditions and other semantically relevant properties to sentence types or their uses. It has been argued that only if they do would it be possible for finite creatures like ourselves to learn them (since the languages involve infinite pairings of sounds and meanings); analogous arguments hold that our ability to understand (in principle) natural languages requires the existence of such semantics. Such arguments apparently presuppose that learning and understanding a language requires knowing a theory from which semantic facts (such as the fact that, for any speaker *x* and time *t*, a use of ‘J’existe encore’ by *x* at *t* says that, at *t*, *x* still exists) are deducible. While such a view is not implausible, alternative plausible views of competence do not support this sort of argument. For example, one might identify linguistic competence with the possession of *syntactic* knowledge (or even just with the possession of syntactic abilities) by someone with appropriate social and environmental relations and behavioural dispositions. Whether natural languages have compositional semantics, and whether the meanings of their sentences are determined simply by the meanings of their parts and syntax, is still not settled.

Computability and information

The standard definition of randomness as considered in probability theory and used, for example, in quantum mechanics, allows one to speak of a process (such as tossing a coin, or measuring the diagonal polarization of a horizontally polarized photon) as being random. It does not allow one to call a particular outcome (or string of outcomes, or sequence of outcomes) 'random', except in an intuitive, heuristic sense. Information-theoretic complexity makes this possible. An algorithmically random string is one which cannot be produced by a description significantly shorter than itself; an algorithmically random sequence is one whose initial finite segments are almost random strings.

Gödel's incompleteness theorem states that every axiomatizable theory which is sufficiently rich and sound is incomplete. Chaitin's information-theoretic version of Gödel's theorem goes a step further, revealing the reason for incompleteness: a set of axioms of complexity N cannot yield a theorem that asserts that a specific object is of complexity substantially greater than N. This suggests that incompleteness is not only natural, but pervasive; it can no longer be ignored by everyday mathematics. It also provides a theoretical support for a quasi-empirical and pragmatic attitude to the foundations of mathematics.

Information-theoretic complexity is also relevant to physics and biology. For physics it is convenient to reformulate it as the size of the shortest message specifying a microstate, uniquely up to the assumed resolution. In this way we get a rigorous, entropy-like measure of disorder of an individual, microscopic, definite state of a physical system. The regulatory genes of a developing embryo can be ultimately conceived as a program for constructing an organism. The information contained by this biochemical computer program can be measured by information-theoretic complexity.

1 The paradox of randomness

Suppose that persons *A* and *B* each give us a string of 32 bits, saying that they were obtained from independent coin flips. If *A* gives the string

$x = 01101000100110101101100110100101$

and *B* gives the string

$y = 00000000000000000000000000000000,$

then we will believe *A* and will not believe *B*: the string *x seems* random, but the string *y* does not. Why? The strings are extremely different from the point of view of regularity. The string *y* has a maximum regularity which allows us to express it in a very compact way - 'only zeros' - while *x* appears to have no shortened definition at all. The distinction between regular and irregular strings becomes sharper as the strings get longer: it is clearly easier to specify the number

$10^{10^{10^{10}}}$

than the first 1,000 digits of π. Classical probability theory is not sensitive to the above distinction, as strings are all equally probable. However, even Laplace (1749-1827) was, in a sense, aware of this paradox; he suggested that non-random strings are strings possessing some kind of regularity, and since the number of all those strings (of a given length) is small, the occurrence of such a string is extraordinary.

Borel (1909), von Mises ([1928] 1919), Ville (1939) and Church (1940) all elaborated on this idea, but a formal model of irregularity was not found until the mid-1960s. Information-theoretic complexity was introduced independently by Solomonoff (1964), Kolmogorov (1965) and Chaitin (1966). The basic idea is to measure the informational complexity of an object by the size of the smallest program computing it. There are two principal applications: (1) to provide a new conceptual foundation for probability theory and statistics by making it possible to define rigorously the notions of random string and random sequence; and (2) to describe the major limitative theorems in mathematical logic in an information-theoretic form.

Let $A = \{a_1, a_2, \ldots, a_Q\}$, $Q \geq 2$, be a finite alphabet, and consider the set of all strings $x_1 x_2 \ldots x_n$ of elements in *A*. We denote by $|x|$ the length of the string *x*.

It is convenient to think of a computer as a decoding device at the receiving end of a communication channel. Its programs can be viewed as code words, or strings over the alphabet *A*, and the result of the computation as the decoded message. It is natural to require that successive programs (for example, subroutines) sent across the channel can be separated. This can be achieved by stipulating that programs are ‘self-delimiting’, that is, no meaningful program is a prefix of another. Self-delimiting programs carry within them information about their size, in the sense that they allow the computer to decide when to stop reading the input; they act as ‘atomic’ programs having no significant sub-programmatic structure. Formally, a ‘computer’ is a self-delimiting partial recursive function *C* which carries strings (programs) into strings (see Computability theory §§2-3). The (Chaitin) complexity $H_C(x)$ of a string *x* induced by the computer *C* is the length of the shortest program for *C* that outputs *x*, and halts:

$$H_C(x) = \min\{|y| \mid C(y) = x\}.$$

This notion of complexity is machine-dependent. It is possible to make it ‘asymptotically’ independent of the choice of the computer. The price paid amounts to at most an $\mathrm{O}(1)$ uncertainty in the numerical values, and is expressed by the following ‘invariance theorem’: there exists a computer *U* such that for all computers *C* one has

$$H_U(x) \leq H_C(x) + \mathrm{O}(1).$$

($\mathrm{O}(f)$ denotes a function $g(n)$ whose absolute value is bounded by a constant times $f(n)$, for sufficiently large *n*.)

A universal self-delimiting Turing machine (see Computability theory §4; Turing machines §2) is a possible candidate for *U*. Indeed, *U* simulates the computation of every computer *C* in the most efficient way: there exists a prefix δ such that the program δx makes *U* simulate the computation of *C* on *x*. The prefix δ depends upon *U* and *C*; it is independent of *x*. From now on we fix a computer *U* (called universal) and put $H_U = H$.

The set of meaningful programs for *U* is an instantaneous code, in the sense that each program can be decoded as soon as we come to the end of the string corresponding to it. In view of the invariance theorem it follows that the set of meaningful programs for *U* is an asymptotically optimal code for the set of all strings: every string can be coded by such a program, with minimum expected length.

In this context the joint complexity $H(x, y)$ of two strings x, y, defined to be the size of the smallest program that makes *U* output both of them, satisfies the classical inequality:

$$H(x, y) \leq H(x) + H(y) + \mathrm{O}(1),$$

that is, the complexity is asymptotically sub-additive. In the original formulation of these definitions the sub-additivity failed to be true. Chaitin (1974) and Levin (1974) independently found the solution: computers have to be self-delimiting.

2 Random strings

Randomness is not absolute, but relative. It makes more sense to ask ‘To what extent is *x* random?’ than ‘What is a random string?’.

To define random strings we try to capture the idea that a string is random if it cannot be algorithmically compressed. Formally, a string is ‘random’ if it has ‘almost’ maximal complexity within the set of all strings of the same length. The maximal value of the complexity of strings of length *n* is given by the formula

$$\max_{|x|=n} H(x) = n + H(\mathrm{string}(n)) + \mathrm{O}(1),$$

where string(*n*) is the *n*th string according to the lexicographic order. (Strings are enumerated in order of increasing length: all strings of length one, followed by all strings of length two, and so on.)

We are naturally motivated to adopt the following definition. A string *x* is (Chaitin) ‘*m*-random’ (*m* a natural number) if

$$H(x) \geq |x| + H(\mathrm{string}(|x|)) - m.$$

x is random if it is 0-random.

To validate the above model of randomness one has to show that random strings defined in this way possess (almost) all properties intuitively associated with randomness. We discuss here only two such properties: (1) the absence of any algorithmic rule for defining random strings; and (2) the equi-distribution of letters and blocks of letters. Property (1) holds true in a strong sense: the set of random strings is 'immune', that is, it is infinite and contains no infinite recursively enumerable subset (see Computability theory §5). The intuition motivating (2) is that in a 'truly random' string each letter has to appear with approximately the same frequency, namely Q^{-1}. Moreover, the same property should extend to substrings. Indeed, one proves that all 'reasonably long' substrings of a random string have approximately the same frequency, which depends only on the length of substrings.

3 Random sequences

An infinite sequence $\mathbf{x} = x_1 x_2 \ldots x_n \ldots$ is uniquely determined by its prefixes

$\mathbf{x}(n) = x_1 x_2 \ldots x_n, \quad n = 1, 2 \ldots .$

Is it possible to define the randomness of a sequence by means of the degree of randomness of its prefixes? The answer is affirmative. A sequence $\mathbf{x}$ is random if and only if there exists a natural number *c* such that $H(\mathbf{x}(n)) \geq n - c$ for all natural $n \geq 1$. This condition is equivalent to the following, apparently stronger, requirement (Chaitin 1974): a sequence $\mathbf{x}$ is random if and only if

$\lim_{n\to\infty} H(\mathbf{x}(n)) - n = \infty.$

Martin-Löf (1966) made use of constructive probability theory in order to define random sequences. The set of all sequences can be equipped with the product probability (induced by the uniform distribution of letters in the alphabet). A constructive null set (of sequences) is a set which can be recursively covered by recursively enumerable sets having arbitrarily small probabilities. The union of all constructive null sets is still a null set, in fact, a maximal one. It can be shown that the set of random sequences coincides exactly with the complement of the maximal null set. It follows that with probability one every sequence is random. However, from a topological point of view, the set of random sequences is of first Baire category, which is a rather small set.

Random sequences share many properties associated with randomness; for instance, they are Borel normal (every string *x* appears in a random sequence with the probability $Q^{-|x|}$, which depends only on the length of the string), they pass almost all stochasticity tests, they are incompatible with the slightest form of computability (the possibility to compute an infinite part of a sequence makes that sequence non-random). Random sequences generate, in a sense, all sequences; that is, every sequence is effectively reducible, via a fixed process, to a random one. Randomness is an invariant of number representations: the usual representations of a real number are either random for all bases, or not so for any base.

4 Chaitin's Omega number

Consider a universal self-delimiting program which, instead of being given a specific program at the beginning of the computation, is fed with a 'random string' of bits. Whenever the universal program requests another input bit we just toss a fair coin and input 1 or 0, according to whether the coin comes up heads or tails. Finally we ask the question 'When the above procedure is begun, what is the probability that the universal program will eventually halt?'. The answer is Chaitin's Omega number, Ω.

The sequence of digits of Ω is random. This means that we will never know more than a handful of digits of Ω. This number appears to be cabalistic: it can be known of, but not itself known.

The fascination of Ω comes from the fact that it is computationally equivalent to the halting problem (see Computability theory §5), but contains the same information in a fantastically compressed form. An oracle supplying a few digits of Ω would be of invaluable help in answering many mathematical questions, such as Goldbach's conjecture (we may construct a computer which halts if and only if it finds an even number greater than 2 which is not the sum of two primes), or Riemann's hypothesis.

From a practical point of view, even having access to all digits of Ω would not make the task of solving problems very easy, as the time (see Complexity, computational) to decompress Ω grows extremely rapidly, that is, non-recursively.

The classical opinion that an axiom should be self-evident appears to be too restrictive. Neither Riemann's hypothesis, nor Schrödinger's equation are self-evident, but both are very useful. The possibility of finding new axioms for the positive integers should perhaps get more attention. This quasi-empirical attitude seems to be consistent with Gödel's own views:

> axioms need not be evident in themselves, but rather their justification lies (exactly as in physics) in the fact that they make it possible for these 'sense perceptions' to be deduced…I think that…this view has been largely justified by subsequent developments, and it is to be expected that it will be still more so in the future.

> ([1944] 1990: 121)

5 Randomness in physics

All science is founded on the assumption that the physical universe is ordered and rational. The most powerful expression of this state of affairs is found in the successful application of mathematics to make predictions expressed by means of the laws of physics. Where do these laws come from? Why do they operate universally and unfailingly? Nobody seems to have reasonable answers to these questions. The most we can do is to explain that the hypothesis of order is supported by our daily observations: the rhythm of day and night; the regular ticking of clocks. However, there is a limit to this perceived order. How are we to reconcile these seemingly random processes with the supposed order? How can the same physical process (for example, the spin of a roulette wheel) obey two contradictory laws, the laws of chance and the laws of physics?

As our direct information refers to finite experiments, it is not out of the question to discover local rules, functioning on large, but finite scales, even if the global behaviour of the process is truly random. But, to perceive this global randomness we have to have access to infinity, which is not physically possible. It is important to notice that, consistently with our common experience, facing global randomness does not imply the impossibility of making predictions. Space scientists can pinpoint and predict planetary locations and velocities 'well enough' to plan missions years in advance. Astronomers can predict solar or lunar eclipses centuries before their occurrence. However, we have to be aware that all these results - superb as they may be - are only true within a certain degree of precision, which can hardly be evaluated.

This suggests the idea that the universe might be random (see Calude and Salomaa 1994). Here is an example illustrating this idea. Consider reversible transformations of a string $x, x_{t+1} = T(x_t)$. This equation can be regarded as a deterministic law of motion generating the phase-space trajectory of a simple, idealized system. The complexity $H(x_t)$ tends to increase in the course of evolution, provided the initial state is not too complex. It approaches the equilibrium value consistently with the Boltzmann estimate of the entropy, and fluctuates around the equilibrium. This shows how a reversible, deterministic, dynamic evolution can lead to a significant increase of complexity (see Zurek 1989).

Any physical system may be perceived as a computational process. One could even go further and speculate (with Wheeler, Fredkin, Toffoli) that the universe is a gigantic information-processing system, in which the output is as yet undetermined. In Wheeler's compact form: 'It from bit!', that is, 'it' - every force, particle, and so on - is ultimately present through 'bits' of information. Under this interpretation Ω - which represents the halting probability of the system - acquires physical significance. This constant is not only non-computable, but reflects, in a sense, the indeterministic, chaotic nature of the universe, consistently with Svozil's thesis (1993) according to which chaos in physics corresponds to randomness in mathematics.

6 Logical depth

Charles Bennett's thesis (1988) is that a structure is 'deep' if it is superficially random but subtly redundant; in other words, if almost all its algorithmic probability is contributed by slow-running programs. The value of a message is only slightly related to its information content. For example, a typical sequence of coin tosses has high information content, but little message value. According to Bennett, the 'logical depth' of a message can be measured by the amount of computational work required by its originator, which its receiver is saved from having to repeat. Here we include things which are computable in principle, but only at a considerable cost in resources. Tolstoy's *War and Peace*, Leonardo da Vinci's portrait of *Mona Lisa*, or phase-space sheets that evolve from simple coarse-grained cells via the chaotic dynamics of a simple Hamiltonian are objects with large logical depth.

Computability theory

*The effective calculability of number-theoretic functions such as addition and multiplication has always been recognized, and for that judgment a rigorous notion of 'computable function' is not required. A sharp mathematical concept was defined only in the twentieth century, when issues including the decision problem for predicate logic required a precise delimitation of functions that can be viewed as effectively calculable. Predicate logic emerged from Frege's fundamental '*Begriffsschrift*' (1879) as an expressive formal language and was described with mathematical precision by Hilbert in lectures given during the winter of 1917-18. The logical calculus Frege had also developed allowed proofs to proceed as computations in accordance with a fixed set of rules; in principle, according to Gödel, the rules could be applied 'by someone who knew nothing about mathematics, or by a machine'.*

Hilbert grasped the potential of this mechanical aspect and formulated the decision problem for predicate logic as follows: 'The Entscheidungsproblem *[decision problem] is solved if one knows a procedure that permits the decision concerning the validity, respectively, satisfiability of a given logical expression by a finite number of operations.' Some, for example, von Neumann (1927), believed that the inherent freedom of mathematical thought provided a sufficient reason to expect a negative solution to the problem. But how could a proof of undecidability be given? The unsolvability results of other mathematical problems had always been established relative to a determinate class of admissible operations, for example, the impossibility of doubling the cube relative to ruler and compass constructions. A negative solution to the decision problem obviously required the characterization of 'effectively calculable functions'.*

For two other important issues a characterization of that informal notion was also needed, namely, the general formulation of the incompleteness theorems and the effective unsolvability of mathematical problems (for example, of Hilbert's tenth problem). The first task of computability theory was thus to answer the question 'What is a precise notion of "effectively calculable function"?'. Many different answers invariably characterized the same class of number-theoretic functions: the partial recursive ones. Today recursiveness or, equivalently, Turing computability is considered to be the precise mathematical counterpart to 'effective calculability'. Relative to these notions undecidability results have been established, in particular, the undecidability of the decision problem for predicate logic. The notions are idealized in the sense that no time or space limitations are imposed on the calculations; the concept of 'feasibility' is crucial in computer science when trying to capture the subclass of recursive functions whose values can actually be determined.

1 Primitive recursive functions

Let us start with the class of 'primitive recursive' functions (from *n*-tuples of natural numbers to the natural numbers). A precise definition of this class was given by Gödel in 1931 (see van Heijenoort 1967), although he then called it simply the class of recursive functions. The main definitional schema of primitive recursion used in the generation of the elements of this class was well-known in mathematics, having been presented most clearly by Dedekind (1888), who had given a set-theoretic reconstruction that turned out to be of importance also in computability theory. Skolem established in 1923 that most functions in elementary number theory are primitive recursive. The foundational significance of this function class was emphasized by Hilbert and Bernays (1934, 1939): the values of the functions (for any argument) can be determined in finitely many steps, proceeding purely 'mechanically'. This point is also expressed by saying that the functions are 'effectively calculable'.

The class $\mathcal{PR}$ of primitive recursive functions is specified inductively and contains as its initial functions the zero-function Z, the successor function S, and the projection functions P^n_i for each *n* and each *i* with $1 \leq i \leq n$. These functions satisfy the equations $\mathrm{Z}(x) = 0$, $\mathrm{S}(x) = x'$ and $\mathrm{P}^n_i(x_1, \ldots, x_n) = x_i$, for all $x, x_1, \ldots, x_n$; x' is the 'successor' of *x*. The class is, first of all, closed under the 'schema of composition': given an *m*-place function ψ and *n*-place functions $\varphi_1, \ldots, \varphi_m$ all in $\mathcal{PR}$, the function ϕ defined by

$$\phi(x_1, \ldots, x_n) = \psi(\varphi_1(x_1, \ldots, x_n), \ldots, \varphi_m(x_1, \ldots, x_n))$$

is also in $\mathcal{PR}$; ϕ is then said to be obtained 'by composition' from ψ and $\varphi_1, \ldots, \varphi_m$. $\mathcal{PR}$ is also closed under the 'schema of primitive recursion': given an *n*-place function ψ and an $(n+2)$-place function φ both in $\mathcal{PR}$,

the function ϕ defined by

$$\phi(x_1,\dots,x_n,0)=\psi(x_1,\dots,x_n)$$
$$\phi(x_1,\dots,x_n,y')=\varphi(x_1,\dots,x_n,y,\phi(x_1,\dots,x_n,y))$$

is also a function in $\mathcal{PR}$; ϕ is said to be obtained 'by primitive recursion' from ψ and φ. A function is 'primitive recursive' if and only if it can be obtained from the initial functions by finitely many applications of the composition and primitive recursion schemas.

The primitive recursive functions do not exhaust the class of effectively calculable functions; that was shown by Ackermann and independently by Gabriel Sudan, who constructed functions that are obviously effectively calculable, but not primitive recursive (see van Heijenoort 1967 for detailed references). The 'Ackermann function' can be defined by the following recursion equations.

$$\phi_0(x,y)=\mathrm{S}(y)$$
$$\phi_{n'}(x,0)=\begin{cases}x & \text{if } n=0\\ 0 & \text{if } n=1\\ 1 & \text{otherwise}\end{cases}$$
$$\phi_{n'}(x,y')=\phi_n(x,\phi_{n'}(x,y))$$

Notice that ϕ_1 is addition, ϕ_2 is multiplication, ϕ_3 is exponentiation, and so on; that is, the next function is always obtained by iterating the previous one. For each *n*, the function $\phi_n(x,x)$ is primitive recursive, but $\phi_x(x,x)$ is not!

We can construct another example of an effectively calculable, but not primitive recursive function ψ by effectively listing all primitive recursive unary functions $\varphi_0,\varphi_1,\varphi_2,\varphi_3,\dots$ and then setting $\psi(x)=1+\varphi_x(x)$. Since ψ differs from every φ_i, ψ cannot be primitive recursive; but the effectiveness of our listing of the functions φ_i ensures that ψ can be effectively calculated.

For working with this class of functions it is indispensable to establish further closure properties. To allow, for example, directly general explicit definitions (without the cumbersome detour of projections) of functions such as

$$f(x,y,z)=(xy+z)^2+789,$$

one establishes that variables can be permuted, substitutions can be carried out, and that the constant functions $\mathrm{con}^n_m(x_1,\dots,x_n)=m$ are primitive recursive. Beyond addition, multiplication and exponentiation it is useful to know that the following functions are also in $\mathcal{PR}$.

$x!$	(factorial)
$\mathrm{pred}(x)$	(predecessor)
$x \dot{-} y$	(arithmetic subtraction, $\max(0,x-y)$)
$\overline{\mathrm{sg}}(x)$	$(=1 \dot{-} x)$
$\mathrm{sg}(x)$	$(=1 \dot{-} \overline{\mathrm{sg}}(x))$

Then it is very easy to define the bounded sum of an $(n+1)$-place function ϕ in $\mathcal{PR}$ as follows.

$$\phi(x_1,\dots,x_n,0)=0$$
$$\sum_{x<y'}\phi(x_1,\dots,x_n,x)=\sum_{x<y}\phi(x_1,\dots,x_n,x)$$
$$+\phi(x_1,\dots,x_n,y).$$

The bounded product is defined similarly.

The functions we listed are useful for the investigation of primitive recursive relations; an *n*-place relation *R* between natural numbers is called primitive recursive if and only if its characteristic function χ_R is in $\mathcal{PR}$. (For recursion-theoretic purposes it is convenient to consider 0 to be the truth-value T and 1 the truth-value F.) It is now possible to show directly that the primitive recursive relations are closed under Boolean operations - particularly, '

$\neg$' (not), 'Čamp;' (and), ' $\vee$' (or), ' $\rightarrow$' (if…then) - and bounded quantification, that is, '($\forall x < y$)' (for all *x* less than *y*) and '($\exists x < y$)' (for some *x* less than *y*).

Finally, we discuss bounded minimization: if for some *x* less than *y* $R(x_1, \ldots, x_n, x)$, then the function $\mu x < y.R(x_1, \ldots, x_n, x)$ yields the smallest such *x*, otherwise the function yields *y*. Define first

$$\phi_1(x_1, \ldots, x_n, x) = \begin{cases} 0 & \text{if } (\exists z \leq x) R(x_1, \ldots, x_n, z) \\ 1 & \text{otherwise} \end{cases}$$

and notice that

$$\mu x < y.R(x_1, \ldots, x_n, x) = \sum_{x<y} \phi_1(x_1, \ldots, x_n, x).$$

Thus, if the relation *R* is primitive recursive, bounded minimization leads to a function in $\mathcal{PR}$.

Given this list of functions in $\mathcal{PR}$ and the closure conditions for primitive recursive relations, we have a convenient framework in which we can show the primitive recursiveness of number-theoretic relations; for example, the characteristic function $\chi_<$ of the 'less than' relation ' $<$' is given by

$$\chi_<(x, y) = \overline{\mathrm{sg}}(y \dot{-} x);$$

equality, being a divisor of, and being prime are all defined easily. This indicates that the class is mathematically rather rich.

2 Finite computations

In 1931 and in his Princeton lectures of 1934, Gödel used primitive recursive functions and relations to describe the syntax of particular 'formal' theories - after Gödel-numbering the syntactic configurations that make up the theory. Since he strove to arrive at a general concept of formality through the underlying concept of calculability for functions, there was no reason to focus attention on theories whose syntax could be presented primitive recursively. He viewed primitive recursive definability of formulas and proofs as a precise condition which *in practice* sufficed to describe formal systems, but he was searching for a condition that would suffice *in principle*.

In his Princeton lectures, Gödel considered it a very important property that the values of primitive recursive functions can be calculated by a finite computation for arbitrary arguments. He added in a footnote:

> The converse seems to be true if, besides recursions according to the scheme (2) [of primitive recursion], recursions of other forms…are admitted. This cannot be proved, since the notion of finite computation is not defined, but it can serve as a heuristic principle.
>
> (1934)

Parenthetically, we note that this remark does not contain a formulation of Church's thesis (see Church's thesis); that (prima facie plausible) reading was explicitly ruled out by Gödel in a letter to Martin Davis (1982). It does, however, indicate the motivation for the considerations in the last part of Gödel's lectures: there he used quite general forms of recursion to introduce 'general recursive functions'. (The relation of Gödel's proposal to suggestions of Herbrand is discussed in Sieg (1994).) These functions are obtained as unique solutions of a system *E* of equations, and their values must be computable in an equational calculus with just two obviously mechanical rules: the first rule allows the substitution of numerals for variables in any equation derived from *E*; the second rule allows the replacement of terms $t(\nu_1, \ldots, \nu_n)$ in a derived equation by μ, in case $t(\nu_1, \ldots, \nu_n) = \mu$ is a derived equation. (Lower-case Greek letters stand here for numerals.)

This class of general recursive functions very quickly turned out to be characterizable in a variety of ways: Church and Kleene showed the equivalence to λ-definability, Kleene to μ-recursiveness (discussed below), and Turing to computability by his machines (see Lambda calculus; Combinatory logic; Turing machines). The class introduced by Gödel was used by Church in his first formulation of 'Church's thesis' (see Sieg 1997). The early, pre-Turing attempts to argue for the thesis are captured in a mathematically concise way through the concept of a function 'reckonable according to rules' (*regelrecht auswertbare Funktion*). These functions were introduced by Hilbert and Bernays in the second volume of their *Grundlagen der Mathematik* (1934, 1939); they were characterized as being calculable in deductive formalisms satisfying general recursiveness conditions; the critical

condition required the proof predicate of the formalisms to be primitive recursive. It was shown that the calculations could be carried out in a particular subsystem of arithmetic; Gödel took this fact in 1946 as the basis for his claim that computability is an 'absolute' concept (see Sieg 1994). The analysis of Hilbert and Bernays also clearly revealed the 'stumbling block' all these analyses encountered: they tried to characterize the elementary nature of steps in calculations, but could not do so without referring to recursiveness (Church), primitive recursiveness (Hilbert and Bernays), or to very specific rules (Gödel).

Only Turing was able, in his ground-breaking 1936 paper 'On Computable Numbers' (see Davis 1965), to circumvent the stumbling block by focusing on the calculations of a human 'computor' proceeding mechanically (see Turing machines §1). He formulated general boundedness and locality conditions for such a computor and showed that any number-theoretic function whose values can be calculated by a computor satisfying these conditions can actually be computed by a Turing machine (see Mundici and Sieg 1995). The latter fact is sometimes called 'Turing's theorem'. The restricted formulation of Turing machines allows a uniform and simple description of computations; its adequacy for linear computations is guaranteed by Turing's theorem. The starting point of Turing's analysis was, however, the mechanical behaviour of a human computor operating on finite configurations in the plane. This behaviour can be described generally and mathematically precisely. To arrive at such a more general description, we take a preliminary step and replace the states of mind by what Turing described as 'physical and definite counterparts'. This is done by considering 'state of mind' not as a property of the working computor, but rather as part of the configuration which is operated on. Turing discussed this replacement very vividly in his 1936 paper:

> It is always possible for the computer [in our terminology, the computor] to break off from his work, to go away and forget all about it, and later to come back and go on with it. If he does this he must leave a note of instructions (written in some standard form) explaining how the work is to be continued. This note is the counterpart of the 'state of mind'. We will suppose that the computer works in such a desultory manner that he never does more than one step at a sitting. The note of instructions must enable him to carry out one step and write the next note.
>
> ('On Computable Numbers', in Davis 1965)

This was achieved quite beautifully by Post in 1947, and Post's approach of describing Turing machine computations is used by Davis (1958). The configurations on which the machine works are instantaneous descriptions (IDs). These are finite sequences in the alphabet of a Turing machine containing exactly one state symbol; the position of the state symbol indicates which symbol is being scanned. A program of a Turing machine can now be viewed as a set of Post production rules operating on (a single symbol of) such IDs. If in this way of describing Turing machines one replaces finite sequences by finite graphs (with a few well-motivated properties) and the simple Post-Turing operations on one symbol at a time by operations on a fixed finite number of distinguished graphs, then one arrives at the notion of a 'Kolmogorov machine'. This latter notion, or rather a general concept of algorithm, was introduced by Kolmogorov and Uspensky (1958): Kolmogorov machines compute exactly the Turing computable number-theoretic functions.

Which number-theoretic functions can be computed by Turing machines or other computing devices? Kleene's analysis of the equational calculus led to the introduction of the 'regular minimization' operator and to an inductive characterization of Gödel's class of general recursive functions. Suppose the $(n+1)$-place function ϕ has the property that for every $x_1, \ldots, x_n$ there is a *y* such that $\phi(x_1, \ldots, x_n, y) = 0$. Denote by $\mu y.\phi(x_1, \ldots, x_n, y) = 0$ the least such *y*. Under these conditions, the function ψ given by

$$\psi(x_1, \ldots, x_n) = \mu y.\phi(x_1, \ldots, x_n, y) = 0$$

is said to be obtained from ϕ 'by regular minimization'. A function is '(μ-)recursive' if and only if it can be obtained from the initial functions by a finite number of applications of composition, primitive recursion and regular minimization. That is, the class $\mathcal{R}$ of recursive functions is obtained from $\mathcal{PR}$ by closure under regular minimization.

Up to now we have considered total (that is, everywhere defined) functions and operations that do not lead outside the class of total functions. Gödel (after Kleene) emphasized the importance of partial functions defined only for a subset of $\mathbb{N}$ or $\mathbb{N} \times \ldots \times \mathbb{N}$. For example, while $\mu y.xy = 0$ is an equivalent definition of the zero function, an

expression such as $\mu y.x + y = 0$ is undefined for each $x > 0$. For partial functions ϕ we liberalize the regularity condition for minimization:

$u = \mu y.\phi(x_1, \ldots, x_n, y) = 0$

holds if and only if the following two conditions are satisfied:

(1) For any $i = 0, 1, \ldots, u - 1,$ $\phi(x_1, \ldots, x_n, i)$ is defined and different from 0;

$\phi(x_1, \ldots, x_n, u) = 0.(2)$

Given $x_1, \ldots, x_n$, at most one number *u* can satisfy both (1) and (2). If no such *u* exists then the *n*-tuple $(x_1, \ldots, x_n)$ is outside the domain of the function

$\mu y.\phi(x_1, \ldots, x_n, y) = 0$

or, stated differently, this function is undefined at $(x_1, \ldots, x_n)$. A function is 'partial recursive' if and only if it can be obtained from the initial functions by a finite number of applications of composition, primitive recursion and (unrestricted) minimization. Note that the partial recursive functions can be enumerated by a partial recursive function; that is obviously not possible in the case of total functions: a standard diagonal construction leads immediately to a contradiction. This fact (for partial recursive functions) and its significance are described in §3 and the beginning of §4.

One can explicitly construct Turing machines for the initial functions and for those operations on programs that correspond to composition, primitive recursion and regular, as well as unrestricted, minimization. Thus, these operations do not lead outside the class of Turing computable functions. This immediately yields the following theorem, showing the power of Turing machines: all partial recursive functions are Turing computable.

3 Effective descriptions

To prove the converse of the theorem just stated, we follow Pythagoras' ontological prescription and use Gödel's device to assign numbers *e* and *y* as 'codes' to Turing machines *M* and finite sequences of IDs. The coding introduced by Gödel for formal theories in 1931 (and adapted for Turing machines in Davis' book) will do. Once a machine is coded as a number, the code can be supplied as an input to any machine; this adumbrates the metamorphosis of hardware into software, culminating in the stored-program computer. Programming the first computers virtually amounted to inserting wires into plugboards, but von Neumann - influenced by Turing's treatment of his paper machines - realized that programs can be coded and stored as strings of symbols in the same way as data.

For any effective Gödel-numbering it is easy, though somewhat tedious, to establish that simple syntactic notions and operations concerning machines and their IDs can be represented by number-theoretic, indeed primitive recursive, predicates and functions. For instance, the ternary predicate $T(e, x, y)$ expressing that *y* is (the code of) a computation of Turing machine (*M* with code) *e* for input *x* is primitive recursive; also, the unary 'result-extracting' function *U* is primitive recursive, where $U(y)$ is either the number on the tape of the last ID of the computation *y* or, in case *y* is not the code of a computation, $U(y) = 0$. (Our choice of the default value 0 is only to guarantee that *U* is a total function.)

Given a Turing computable function ϕ and a machine *M* with code *e* computing ϕ, there are two possibilities for any input *x*:

Case 1. M terminates. Then there is a (first) computation y^* of *M* for input *x*, that is, y^* is the smallest number *y* such that $T(e, x, y)$; the number $U(y^*)$ read on the tape in the final configuration of y^* coincides with the value $\phi(x)$; writing $\mu y.T(e, x, y)$ as an abbreviation for $\mu y.\chi_T(e, x, y) = 0$, we have

$\phi(x) = U(\mu y.T(e, x, y)).(3)$

Case 2. M does not terminate. Then for any *y*, the predicate $T(e, x, y)$ will be false, that is, $\chi_T(e, x, y) = 1$ for all *y*, and condition (2) in the definition of the unrestricted μ-operator will never hold. Thus, both $\mu y.T(e, x, y)$ and $U(\mu y.T(e, x, y))$ are undefined.

This establishes (3) for both cases, and we have proved 'Kleene's normal form theorem' for unary Turing computable functions:

Let φ be an *n*-place number-theoretic function that can be computed by a Turing machine with code *e*; then for each $x_1, \ldots, x_n$ in the domain of φ we have
$\varphi(x_1, \ldots, x_n) = U(\mu y.T(e, x_1, \ldots, x_n, y)).$

Kleene's theorem holds also, with the same proof, for functions having any finite number of arguments. Kleene established this normal form theorem not for Turing computable functions, but for total functions that can be calculated in Gödel's equational calculus. He concluded that Gödel's general recursive functions are recursive, a conclusion we can draw now for Turing computable partial functions: every Turing computable function is partial recursive.

Using the theorem formulated at the very end of §2, it follows that Turing computability for number-theoretic functions is equivalent to partial recursiveness and, indeed, to all the other characterizations discussed in that section. Kleene's theorem has most interesting additional consequences, to be discussed in the next section. This is done not just to present elegant mathematical results, but to reinforce the conceptual analysis, as these results (are taken by some to) lend additional support to Church's thesis (see Church's thesis).

4 Basic results

Kleene's normal form theorem has important consequences for the theory of computability. Consider, first of all, the two-place function

$\psi(e, x) = U(\mu y.T(e, x, y));$

ψ is partial recursive and provides an enumeration of all unary partial recursive functions. This is 'Kleene's enumeration theorem'. This theorem - together with the equivalence of partial recursiveness and Turing computability - guarantees the existence of a 'universal' Turing machine. Indeed, consider a Turing machine $M[\psi]$ computing ψ. For any pair of arguments *e* and *x*, $M[\psi]$ interprets its first argument as the code of a Turing machine $M[\varphi]$ (computing a unary partial recursive function φ) and its second argument as the input for $M[\varphi]$. Then $M[\psi]$ proceeds to compute $\varphi(x)$ following the program of $M[\varphi]$. Since $M[\varphi]$ was arbitrary, $M[\psi]$ is able to simulate any Turing machine. Similarly, for each $n = 2, 3, 4, \ldots$, there is a partial recursive $(n+1)$-place function $\psi^{(n)}$ such that every *n*-place partial recursive function φ can be written as

$\varphi(x_1, \ldots, x_n) = \psi^{(n)}(e, x_1, \ldots, x_n)$

for a suitable index *e* for φ.

Given a function $\varphi(p_1, \ldots, p_m, x_1, \ldots, x_n)$ of $m+n$ variables, let us 'parametrize' φ, that is, assign values $p_1^*, \ldots, p_m^*$ to the first *m* variables. We then obtain a new *n*-place function ϕ as follows:

$\phi(x_1, \ldots, x_n) = \varphi(p_1^*, \ldots, p_m^*, x_1, \ldots, x_n).$

Intuitively, ϕ is the 'slice' of φ with coordinates $(p_1^*, \ldots, p_m^*)$. By Kleene's enumeration theorem we can write, for suitable indices *e* and e^*:

$$\varphi(p_1, \ldots, p_m, x_1, \ldots, x_n) = \psi^{(m+n)}(e, p_1, \ldots, p_m, x_1, \ldots, x_n)$$

and

$\phi(x_1, \ldots, x_n) = \psi^{(n)}(e^*, x_1, \ldots, x_n).$

The following 'parameter (or S_n^m-) theorem' tells us that the slicing operation leading from *e* to e^* can be performed uniformly and effectively:

For each $m, n > 0$ there is a primitive recursive $(n+1)$-place function S_n^m such that

$$\psi^{(m+n)}(e, p_1, \ldots, p_m, x_1, \ldots, x_n)$$
$$= \psi^{(m)}(\mathrm{S}_n^m(e, p_1, \ldots, p_m), x_1, \ldots, x_n).$$

This theorem was established by Kleene at first for Gödel's general recursive functions; it amounts in that context to replacing effectively the first *m* variables of the function φ computed from equations with code *e* by numerals for $p_1, \ldots, p_m$. This theorem is used to prove the following central result, also due to Kleene, the 'recursion theorem':

Let ϕ be a partial recursive function with $(n+1)$ places. Then there is a number *e* such that for all $x_1, \ldots, x_n$

$$\psi^{(n)}(e, x_1, \ldots, x_n) = \phi(e, x_1, \ldots, x_n).$$

The theorem finds many uses in establishing that implicitly defined functions are actually partial recursive. For example, letting $n = 1$ and writing ψ instead of $\psi^{(1)}$, an application of the recursion theorem to the function $g(y, x) = y$ immediately yields the 'fixed point theorem':

There is a constant e^* such that for all *x*

$$\psi(e^*, x) = e^*.$$

Intuitively, for every possible input *x*, the program with number e^* uses *x* to output a copy of itself - just like a self-replicating organism. More generally, for every recursive function $r(z)$, we obtain by applying the recursion theorem to the function $\psi(r(z), x)$ a number *e* such that for all *x*, $\psi(e, x) = \psi(r(e), x)$.

Kleene's enumeration theorem allows us to reformulate properties of partial recursive functions as number-theoretic properties of their codes. A set *P* of natural numbers is called an 'input-output property' (of unary partial recursive functions) if and only if, whenever e' is in *P* and e'' codes the same function as e' (in the sense that $\psi(e', x) = \psi(e'', x)$ for all *x* in their common domain), then e'' is also in *P*. The following theorem, 'Rice's theorem', states that non-trivial input-output properties are not recursive: if *P* is an input-output property such that neither it nor its complement is empty, then *P* is not recursive.

There are important non-trivial input-output properties of programs. For instance, the set of codes of Turing machines computing total functions is one such property; as a consequence of Rice's theorem we know that there is no Turing machine that decides whether or not a given Turing computable function is total. We will discuss additional undecidable problems in the next section; however, undecidability will be established there in quite different ways.

5 Undecidable problems

'Problems' are identified with (characteristic functions of) one-place predicates or, equivalently, with subsets of $\mathbb{N}$. Let *K* be the problem corresponding to the question 'Does the computation of machine *M* with code *e* terminate, if the input is the natural number *e*?'. This problem was formulated by Turing and is known as the 'halting problem' (see Turing machines §3). A diagonal argument (using the existence of a universal machine) settles the undecidability of *K* without resorting to Rice's theorem.

The halting problem is the progenitor of a multitude of undecidable problems, arising in virtually all fields of mathematics. Consider, for instance, the following problem. Let there be a presentation *P* of a group *G* via generators and relations (*P* looks like a multiplication table for *G*) and two expressions *v* and *w* built up from these generators, using the multiplication operation and its inverse. Do *v* and *w* represent the same element of *G*? This is known as the 'word problem for groups'. Novikov and, independently, Boone proved that the problem is undecidable.

Markov proved the undecidability of the following problem for four-dimensional manifolds. Consider a suitable combinatorial description of two manifolds. Are they homeomorphic? In the two-dimensional case the problem becomes decidable; it is not known whether the three-dimensional problem is decidable or not.

Yet another logic-free undecidable problem is given by elementary functions, that is, those functions *f* of a real variable *x* which can be built up using exponentials, logarithms, *n*th roots, trigonometric functions and their

inverses by addition, multiplication, and composition. While the derivative operation does not lead outside the realm of elementary functions, the integral of, say, $(\sin x)/x$ is not elementary. Indeed, Richardson proved that the following problem is undecidable: is the integral of an elementary function elementary?

Finally, the tenth problem in Hilbert's list presented at the International Congress of Mathematicians in 1900 asks for an algorithm to decide of a Diophantine equation - that is, a polynomial equation $p(x_1, \ldots, x_n) = 0$, with integer coefficients - whether or not it has integer solutions (see Hilbert 1900). Following important work by J. Robinson, Davis and Putnam, Matijasevic proved in 1970 that this problem is undecidable (see Matijasevic 1993).

Let us go back to the halting problem, *K*. Recalling the discussion in §3, it is clear that the predicate $K(e)$ can be defined by the statement 'There exists a *y*, such that $T(e, e, y)$'. *K* is thus an example of a 'recursively enumerable' (RE) set of natural numbers: it can be defined by prefixing one existential quantifier to a decidable binary predicate. Trying for each *n* in $\mathbb{N}$ all possible pairs (e, y) such that $e + y = n$ and singling out *e* whenever $T(e, e, y)$ is true, we can effectively list all members of *K*. Recursively enumerable sets were named because of the following equivalent characterization: a subset of $\mathbb{N}$ is RE if and only if it is either empty or the range of a (primitive) recursive function. Furthermore, a set *R* is recursive if and only if both *R* and its complement are RE. This latter fact allows a different route into computability theory: recursive enumerability is taken as the basic concept, and recursive sets are defined as those RE sets whose complements are also RE; this is done in Post's approach.

The importance of *K* among RE sets stems from its being 'complete', that is, maximally difficult among all RE sets; by this we mean that every RE set can be effectively reduced to *K*. A problem *P* is effectively reducible to *Q* if and only if there is a recursive function *f* such that for all natural numbers *x*, $x \in P$ if and only if $f(x) \in Q$. Thus, if we want to see that *x* is a solution of problem *P* we compute $f(x)$ and test whether $f(x)$ solves *Q*! Clearly, *Q* is at least as difficult as *P*, in the sense that effective solutions for *Q* yield effective solutions for *P*. By effectively reducing the halting problem *K* to the *Entscheidungsproblem* (decision problem) *E*, Turing concluded from the undecidability of *K* that also *E* cannot be decidable. Turing's reduction is nothing but a transcription of the ternary predicate $T(e, e, y)$ into a first-order arithmetical theory with sufficient demonstrative power.

The halting problem *K*, the most complex among RE problems, is the simplest in an infinite sequence of manifestly undecidable problems, the so-called 'jumps'. In order to obtain the jump hierarchy, the concept of computation is relativized to sets of natural numbers whose membership relations are revealed by 'oracles'. The jump K' of *K*, for example, is defined as the halting problem, when an oracle for *K* is available. This hierarchy can be associated in a most informative way with definability questions in the language of arithmetic: all jumps can be defined by increasingly complex arithmetical formulas, and all arithmetically definable sets are reducible to some jump. The above construction underlies the arithmetic hierarchy introduced by Kleene and Mostowski in the fifties.

Certain interesting sets of natural numbers are not definable by arithmetic formulas; one example is the set of all Gödel numbers of true arithmetic statements. If this set were arithmetically definable, one could formulate arithmetically the liar sentence that expresses its own falsity. This observation of Gödel and Tarski (see Gödel's theorems) is the cornerstone for proving the incompleteness of every formal theory of arithmetic that contains symbols for addition and multiplication and has semantically sound axioms and rules of inference: no matter which (true) statements we choose as axioms, and no matter which inference rules we adopt (provided they are truth-preserving) there are statements which, albeit true for the natural numbers, are not provable in the theory. Arithmetic truth can be defined, however, in second-order languages that allow quantification over functions.

6 Physical steps

Turing appealed in his analysis of mechanical calculability to the limitations of the human sensory apparatus; he claimed that the justification for his thesis lies ultimately 'in the fact that the human memory is necessarily limited'. This remark is not expanded on at all, and we can only speculate as to Turing's understanding of this 'fact': did he have in mind more than the spatial limitations for 'encoding' finite configurations? If not, the restrictions can be motivated by physical considerations. The question of whether there are ways of getting around the effect of such physical limitations is discussed with references to the literature by Mundici and Sieg (1995); and Mundici (1981).

Assume that a Kolmogorov machine operates on configurations containing *z* different symbols, each symbol being physically 'coded' by at least one atom - an altogether reasonable assumption. Then there must be at least *z* pairwise disjoint regions containing the codes (of the symbols). Otherwise, the electron clouds of two different codes might overlap, making the codes indistinguishable. Let c and a denote the speed of light and Bohr's radius of the hydrogen atom, respectively, so that $\mathrm{a}/\mathrm{c} = 0.176 \times 10^{-18}$ seconds. It follows that the codes will be contained in a volume of at least $z(4/3)\pi \mathrm{a}^3$ cubic metres; that forces the diameter of the machine to be larger than $2\mathrm{a}z^{\frac{1}{3}}$ metres - the diameter being the largest possible distance between two codes in this volume. Let *f* be the frequency of our machine; thus, $1/f$ is the time available for each computation step. Since signals cannot travel faster than light and since a computation step involves the whole configuration, it follows that *f* cannot exceed $\mathrm{c}/(2\mathrm{a}z^{\frac{1}{3}})$ steps per second. Thus, we obtain the inequality

$$fz^{\frac{1}{3}} < 2.828 \times 10^{18} \text{ steps per second},$$

which points out a fundamental incompatibility between high number of codes (that is, size of configurations) and high computational speed. The operations of Kolmogorov machines are thus restricted in complexity, as they have to lead from distinguished graphs to distinguished graphs; and within the given physical boundaries only finitely many different graphs are realizable.

If we focus on physical devices and analyse machine, not human mechanical, computability we have to take into account the possibility of parallel procedures as incorporated, for example, in cellular automata. Gandy (1980) provided the first conceptual analysis and a general description of parallel algorithms. These algorithms are thought to be carried out by 'discrete deterministic mechanical devices', that is, machines satisfying the physical assumptions explicit in our discussion above; in Gandy's words,

> The only physical assumptions made about mechanical devices…are that there is a lower bound on the linear dimensions of every atomic part of the device and that there is an upper bound (the velocity of light) on the speed of propagation of changes.
>
> (1980: 126)

He formulated axiomatic principles for these devices and proved that whatever can be calculated by devices satisfying the principles ('Gandy machines') is also computable by a Turing machine.

Computer science

At first sight, computers would seem to be of minimal philosophical importance; mere symbol manipulators that do the sort of things that we can do anyway, only faster and more conveniently. Nevertheless, computers are being used to illuminate the cognitive abilities of the human and animal mind, explore the organizational principles of life, and open up new approaches to modelling nature. Furthermore, the study of computation has changed our conception of the limits and methodology of scientific knowledge.

Computers have been able to do all this for two reasons. The first is that material computing power (accuracy, storage and speed) permits the development and exploration of models of physical (and mental) systems that combine structural complexity with mathematical intransigence. Through simulation, computational power allows exploration where mathematical analysis falters. The second reason is that a computer is not merely a concrete device, but also can be studied as an abstract object whose rules of operation can be specified with mathematical precision; consequently, its strengths and limitations can be systematically investigated, exploited and appreciated. Herein lies that area of computer science of most interest to philosophers: the theory of computation and algorithms. It is here where we have learned what computers can and cannot do in principle.

1 Turing machines and computability

In his classic paper 'On Computable Numbers, with an Application to the *Entscheidungsproblem*' (1936) Alan Turing investigated the problem of characterizing the computable real numbers. The real numbers are those numbers that correspond to the points on a straight line: the positive and negative integers, the fractions or rational numbers, and finally, the irrational numbers, such as π and the square root of 2. Whereas the values of the integers and fractions can be specified using a finite set of symbols and computed exactly, the same is not true for the irrationals. Some of the irrationals like π or the square root of 2 can be computed to as many decimal places as we like; other irrationals, however, cannot be computed at all. Intuitively, the difference between the two kinds of numbers lies in the fact that the former can be determined to arbitrarily high degrees of precision, in Turing's words, 'using finite means', whereas to obtain an arbitrarily precise value of the latter sort of number would require infinite means.

Turing proceeds to give a precise account of what it means to compute 'using finite means'. Imagine a machine that at any given time is in one of a finite number of states $Q = \{q_0, q_1, \ldots, q_i\}$. At the same time, the machine is scanning a square of a finite but extendible tape on which is printed one of a finite number of symbols $S = \{s_0, s_1, \ldots, s_k\}$. The machine is capable of doing just three things. First, it writes a symbol on the square (possibly the same symbol that it is scanning). Next, it moves one square to the left or one square to the right. And finally, it enters a (possibly) new state. The key idea is that what the machine does is determined only by its current state and the symbol currently being scanned. Exactly what the machine is to do in a given situation is specified by a rule which is stated in the form of a 'quintuple' such as the following:

$q_2 \; * \; \# \; R \; q_3,$

which may be read, 'if in state q_2 and scanning the symbol *, then write the symbol #, go to the right and enter state q_3'. A Turing machine is formally defined as a set of such instructions, subject to the proviso that no two quintuples begin with the same two items. (This ensures that there is no ambiguity as to what the machine is to do when in a certain internal state and scanning a given symbol.) Often, the state q_0 is designated as the starting state of the machine, and the symbol s_0 is considered to be the 'blank' symbol *B*. A Turing machine halts when it is in a certain internal state q_i, scanning a symbol s_i, and there is no quintuple beginning with $q_i s_i$. (What to do, what to do…?) Using these conventions, and assuming that the machine is started on the right-most symbol of a finite string of 1s, then the machine described by the quintuples:

$q_0 \; 1 \; 1 \; L \; q_0$

$q_0 \; B \; 1 \; L \; q_1$

will (as the reader can verify easily) move to the left leaving all of the 1s intact until it finds the first blank ('*B*') which it will then replace by a 1, move one more square to the left, and then halt (see Turing machines).

Let us call the symbols $\mathbf{S}^* = \{s_1, s_2, \ldots, s\}$ the (proper) *alphabet* of the Turing machine. (Notice that the 'blank' symbol q_0 is hereby excluded.) The *words* of this alphabet are now defined as the set of all the finite strings of the members of the alphabet. A function on this alphabet is simply a map that takes any word to a unique word; that is, a map from the set *words* to itself. (For simplicity's sake, only functions taking a single argument will be considered here.) Such a function is said to be *Turing computable* just in case there is a Turing machine *M* which, when started on the right-most letter of a word, eventually halts leaving on its tape the string that is the function's value on the original word. Roughly, a Turing computable function is a function that can be computed by some Turing machine.

Of all the functions on an alphabet, how many are Turing computable? With the aid of Cantor's theory of infinite sets (see Cantor's theorem), we can answer this question fairly easily. Basically, since a Turing machine is determined by (and can thus be regarded as defined by) a finite set of quintuples, Turing machines can (in principle) be ordered 'alphabetically'. So there are only a countable infinity of Turing machines and hence at most a countable infinity of Turing computable functions (since each Turing computable function requires at least one Turing machine to compute it). But there are an uncountable infinite number of functions from (any) set of words to itself. Hence, although there are an infinite number of Turing computable functions, there are an uncountable number of functions that are not Turing computable. So to the question, 'of all the functions from words to words, how many are computable?', the answer is 'a countable infinity, that is, almost none of them'. Later, we shall examine an interesting function - the Halting function - that is not computable.

Although we have considered functions from and to the words of any finite alphabet of symbols, the same results may be obtained by confining our attention to functions from the set *N* of natural numbers $0, 1, 2, \ldots$, to itself. To see this, think of the symbols $\mathbf{S}^* = \{s_1, s_2, \ldots, s\}$ as the digits $\{0, 1, \ldots, i-1\}$. Then, corresponding to a finite string of letters in $\mathbf{S}^*$, we have a string of digits, which can then be regarded as representing a natural number using base *j*. In this way, the words of $\mathbf{S}^*$ become mapped to numbers in *N*, and functions from *words* to *words* become functions from *N* to *N*. This allows us to restrict our attention to the Turing computable functions from *N* to *N* without any important loss of generality.

2 The Church-Turing thesis

In work carried out prior to Turing's 1936 paper (presented to the American Mathematical Society in 1935), Alonzo Church (1936) had defined a class of computable functions from the set $N = \{0, 1, 2, \ldots\}$ of natural numbers to itself which he called the 'recursive' functions. The recursive functions are defined, roughly, as those that can be obtained from a few basic computable functions (in the sense that we have algorithms for them) by applying 'computable' operations such as functional composition or recursion. For example, one of the basic functions is the *successor* function which takes a number *n* to $n+1$. Another is multiplication. Composing these two functions we obtain $(n+1)m$. Church's basic functions, Turing showed, were Turing computable, and the operations for their combination could also be mimicked by Turing machines. For example, the function $mn+1$ can be computed by a Turing machine that chains together the Turing machines that compute *mn* and $n+1$. In this way, Turing showed that the recursive functions are all Turing computable. In addition, he also proved the converse: any Turing computable function from *N* to *N* is recursive. As a result, the Turing computable functions and the recursive functions are identical (Boolos and Jeffrey 1982, chs 7 and 8).

In his 1936 paper, Church had conjectured that the recursive functions were just the computable functions from and to the natural numbers *N*. In his paper of the same year, Turing also conjectured that the functions computable by his machines were also just the computable functions. Since the two sets of functions are identical, these conjectures have since been joined and are known as the *Church-Turing thesis*, namely,

Any computable function from N *to* N *is recursive, that is, Turing computable* (see also Church's thesis).

Let us see what reasons there are for holding this thesis to be correct.

First of all, notice that in the above statement of the thesis, the first occurrence of the term 'computable' has not been given a precise definition. The intuitive idea is that a function is computable if we can calculate its output using means that are of the same sort that we use to do calculations in arithmetic. But what, exactly, are these 'means'? We have examples galore, but no precise general account of what sort of procedures these examples

embody. We could, of course, simply take Church's recursive functions or Turing's machine to *define* just those procedures. But in that case, the Church- Turing thesis becomes a tautology.

So let us stick with 'computable' as a pre-analytic term and see where that gets us. Consider the following example. Suppose that we consider a new kind of machine model, very much like a Turing machine, except that instead of a one-dimensional tape, the new machine operates on a 'board' of two dimensions, a potentially infinite checkerboard. Such a *2D Turing machine*, as I shall call it, will have quintuples just like a Turing machine, except that the move instructions *R*, *L* are expanded to eight possibilities: *N*, *S*, *E*, *W*, *NE*, *NW*, *SE*, and *SW*. Imagine that we now write out a set of quintuples and proceed to use them in the same way that we previously used a Turing machine - say, to determine what results from putting the string !#* down on the board and starting at the eastmost symbol (*). Clearly, if we could show that such a machine would stop when provided with any such input, then we would agree that a function was thereby *computed* by this 2D Turing machine. In short, the same intuitions which assure us that any function which is Turing computable is *computable* in the ordinary sense - the uncontested converse of the Church-Turing thesis - also work here to yield the conviction that any function that is 2D Turing machine computable is *computable*. But if this be granted, it can now be seen that there is - at least in principle - a way to show the *falsity* of the Church-Turing thesis: produce a machine model, such as a 2D Turing machine, that clearly *computes*, and then prove that there are some functions that *it* can compute that a standard Turing machine cannot.

In this spirit (and perhaps just for the fun of it), there has been a great deal of work on developing alternative models of computation. The 2D Turing machine model given above, along with its *n*-dimensional counterparts, can be shown to be no more powerful than a standard linear tape machine. Adding finitely many tapes with their own read/write heads does not help either: any function computable by these enhanced machines can be proven to be computable (perhaps more slowly) by a lowly standard Turing machine. Other models that are not simple variations of Turing machines have also been explored, such as abacus or register machines, post systems and generalized digital computers. While these alternative models might usefully focus on one or more features of computation systems, they all are incapable of computing a function that cannot likewise be computed by a 'plain vanilla' Turing machine. As a result, although there is no way of proving the Church-Turing thesis to be correct, it is widely held to be so.

The Turing machines that we have considered so far have all been dedicated to some particular computational task. A *universal Turing machine* (UTM) would be capable of computing anything that a Turing machine can. In his 1936 paper, Turing showed how to construct machines of this type, and, roughly, here is how they work. A section of the tape of a UTM is set aside (perhaps surrounded by *s or some other symbol in its alphabet reserved for this purpose) for the program that the machine is to execute. This program will be another Turing machine's quintuples (probably suitably encoded). A suitable input is now provided in some input area of the tape, and the UTM passes back and forth from the program and input areas to the work area, performing the computation in accord with the program on its tape. When one considers that much the same sort of activity is precisely what undergraduates do when, in a purely mechanical way, they work out on paper the behaviour of a Turing machine provided by the instructor, then the existence of a universal Turing machine should not come as much of a surprise. What is more remarkable is that such a machine is described in some detail in Turing's 1936 paper. Later work has produced some very concise UTMs, such as Marvin Minsky's, which uses only four symbols and seven states (Minsky 1967: §14.8). Turing's basic idea - put the program on the tape (in the temporary memory, RAM) of a universal computer - was later taken up by von Neumann, and became one of the pillars of current digital computer architecture.

3 The Halting problem

As we have already seen, 'most' functions from *N* to *N* are not computable. Let us now look at a particular function that bears this affliction, the Halting function. Given a particular Turing machine or more generally, a particular program, it would be useful to be able to know whether that program will halt when provided with a given input. Of course, in some cases, the answer is obvious. The problem here is to find a general method, another program, that can compute the answer to the halting problem for *any* given input program and its input. Putting the matter in terms of Turing machines: is there a Turing machine that, when provided with a (suitably encoded version of a) program on its tape, together with an input to that program, will output, say, a '1' if the program will

halt on that input and a ‘0’ otherwise. (It is assumed here that, after delivering its verdict, the Halter machine itself then halts.)

It turns out that no such Turing machine exists. This result is sometimes referred to as the undecidability of the Halting problem. One reason this is so important is that it is the basis of showing that a number of other such problems are undecidable (by reducing them to the Halting problem); another reason is that it shows that there is a strong connection between the failure of computability and a wide class of unsolved problems in number theory. For example, in 1742 Goldbach conjectured that every even number (greater than 2) can be expressed as the sum of two prime numbers; to this day, his conjecture has been neither proven nor disproven. Now it is a simple matter to write a program that will check an even number to see if it is expressible as the sum of two primes, and do this for successively greater even numbers. If such a program were to find an even number not equal to the sum of two primes, then it could be designed to halt and print out some message like ‘Goldbach has been refuted!’. On the other hand, if Goldbach was right, then the program will go on checking even numbers indefinitely, and thus never halt. If the Halting problem were decidable, then such problems - and there are a great many such problems - could (in principle, at least) be settled according to the Leibnizian saying: ‘Let us compute!’ (For a survey of results on uncomputable functions, see Harel 1992, ch. 8.)

4 Problems that are computationally intractable

Even when we consider only computable functions, there are some problems whose solutions will probably forever remain beyond our reach. A classic example is the travelling salesperson problem. Imagine a set of *N* towns laid out on a map, together with the various roads connecting these towns. The length of each road is given. The problem now is to find the shortest itinerary for the salesperson to take which starts at a given town, returns to that town at the finish, and visits every other town exactly once. Clearly, the solution is computable: enumerate each of the possible paths, computing and recording its length along the way, and return as the answer the path requiring the minimum total distance. The problem is that the number of steps required to execute this algorithm goes up drastically as the number of towns involved gets larger. Thus, for 100 towns, the number of steps required by the best current programs is greater than 2^{100}, a very large number. (Assuming our algorithm executes one million steps per second, such an algorithm would require over 10^{16} years to complete its task; the accepted upper limit on the age of the universe is, however, only around 15 billion, that is, 15×10^9 years.)

The travelling salesperson problem is only one of a wide class of problems, called *NP complete* problems, that require, as far as we know, solutions on the order of *N* steps. (The reason that *NP* complete problems are so-called may be found in Harel 1992, ch. 7.) If any one of the problems in this class could be shown to be solvable by an algorithm that was, say, linear in *N* or polynomial in *N*, then the same would be true for all the problems in this class. While it is widely believed that the *NP* complete problems require algorithms that work in exponential time, this has not yet been proven, and remains one of the most difficult unsolved problems in the theory of computation.

Problems having an input of size *N* that *require* 2^N or more steps for their solution are said to be *intractable*. While there remains some (dim) hope for the tractability of the *NP* complete problems, there are many other problems that are provably intractable, and thus require algorithms operating in exponential time or worse. For example, a complete examination of the game tree of checkers could determine whether or not the side that moves first has a guaranteed winning strategy. Consider now generalized checkers, played not on an 8×8 board, but on an $N \times N$ board. It has been shown that the problem of determining the existence of a guaranteed first-mover winning strategy is intractable in *N*; that is, there is no algorithm for solving this problem which does so in fewer than K^N steps $(K > 1)$. This is not the end of it, however. Some problems can be shown to be solvable in at best doubly exponential time 2^{2N}, or even worse. Similar results have been established for problems that involve unreasonably large amounts of memory space (Harel 1992, ch. 7).

The situation is not altogether bleak. There are tractable algorithms for solving *NP* complete problems that give correct or nearly correct answers most of the time. For example, there are tractable algorithms designed to tackle the travelling salesperson problem that routinely come up with paths that are surely far shorter than most routes. Another possible way around intractability is an algorithm that generates the correct answer (say, to a decision problem) with a certain high probability, regardless of the size *N* of the input. More precisely, suppose that we can show that if the answer to our question is truly ‘yes’, then there is an algorithm that will output ‘yes’ with a

probability $P > K$, regardless of the size *N* of the input; on the other hand, if the correct answer is 'no', then our algorithm will quickly yield that result. Clearly, such an algorithm is almost as good as one that provides answers whose correctness can be guaranteed.

One such probabilistic algorithm was presented by Solovay and Strassen (1977). It is designed to test an arbitrary natural number for compositeness. (Does the number have nontrivial factors?) Number theorists have been able to show that if a number is composite (that is, not prime), then over half of the numbers less than that number will have a quickly computable property *W* that will be a conclusive witness to that fact. Thus if a number is not composite, no such witness will exist. A candidate *N* for compositeness is now input into the algorithm and a number less than *N* is chosen at random. If the randomly chosen number has the 'witness' property *W*, then the original number *N* must be composite, so the program outputs 'Composite!' and halts. On the other hand, if the randomly chosen number does not have the witness property *W*, then the algorithm chooses another number less than *N* at random. If 100 or so random choices fail to turn up a witness to *N*s compositeness, then the program outputs 'Not composite!'. A little thought shows that since over $1\colon 2$ of the numbers less than *N* will have *W* if *N* is composite, then if we fail to find such a witness after 100 random trials, the chances of *N*s being composite are less than $1\colon 2^{100}$, a very small chance indeed. Provided we are willing to take a small risk of error, this method results in a very fast probabilistic algorithm for testing compositeness.

Whether the existence of such an algorithm shows that probabilistic algorithms can tame intractable problems is, however, still unclear. The hitch is that the compositeness problem is not *known* to be intractable. Furthermore, there are no cases of problems *known* to be intractable that have succumbed to a probabilistic algorithm (although some *NP* complete problems have been tamed). The issue of whether or not there are probabilistic algorithms that can solve (provably) intractable problems remains open. It *has* been shown, however, that probabilistic algorithms cannot tame problems that are not computable, a result that follows from the fact that any probabilistic algorithm can be simulated deterministically.

The theory of deterministic algorithms has also contributed to our understanding of what apparently stands in direct opposition to determinism: randomness (see Randomness §4).

Comte, Isidore-Auguste-Marie-François-Xavier (1798-1857)

The French philosopher and social theorist Auguste Comte is known as the originator of sociology and 'positivism', a philosophical system by which he aimed to discover and perfect the proper political arrangements of modern industrial society. He was the first thinker to advocate the use of scientific procedures in the study of economics, politics and social behaviour, and, motivated by the social and moral problems caused by the French Revolution, he held that the practice of such a science would lead inevitably to social regeneration and progress.

Comte's positivism can be characterized as an approach which rejects as illegitimate all that cannot be directly observed in the investigation and study of any subject. His system of 'positive philosophy' had two laws at its foundation: a historical or logical law, 'the law of three stages', and an epistemological law, the classification or hierarchy of the sciences. The law of three stages governs the development of human intelligence and society: in the first stage, early societies base their knowledge on theological grounds, giving ultimately divine explanations for all phenomena; later, in the metaphysical stage, forces and essences are sought as explanations, but these are equally chimerical and untestable; finally, in the positive or scientific stage, knowledge is secured solely on observations, by their correlation and sequence. Comte saw this process occurring not only in European society, but also in the lives of every individual. We seek theological solutions in childhood, metaphysical solutions in youth, and scientific explanations in adulthood.

His second, epistemological law fixed a classification or hierarchy of sciences according to their arrival at the positive stage of knowledge. In order of historical development and thus of increasing complexity, these are mathematics, astronomy, physics, chemistry, biology and sociology. (Comte rejected psychology as a science, on the grounds that its data were unobservable and therefore untestable.) Knowledge of one science rested partly on the findings of the preceding science; for Comte, students must progress through the sciences in the correct order, using the simpler and more precise methods of the preceding science to tackle the more complex issues of later ones. In his six-volume Cours de philosophie positive (The Positive Philosophy) (1830-42), Comte gave an encyclopedic account of these sciences, ending with an exposition of what he regarded as the most advanced: social physics or 'sociology' (a term he invented). The sociologist's job would be to discover the laws that govern human behaviour on a large scale, and the ways in which social institutions and norms operate together in a complex yet ultimately predictable system.

In his later work, Comte fleshed out his vision of the positive society, describing among other things a Religion of Humanity in which historical figures would be worshipped according to their contribution to society. Despite such extravagances, however, the broader themes of his positivism - especially the idea that long-standing social problems should be approached scientifically - proved influential both in France and, through J.S. Mill's early support, in England.

1 Life

Auguste Comte was born in Montpellier, France. He attended the École Polytechnique, from which he was expelled in 1816, for political reasons. Comte's main concern throughout his life was resolving the political, social and moral problems caused by the French Revolution. To that end, he embarked upon an encyclopedic work, which he first conceived under the inspiration of Henri de Saint-Simon, for whom he worked as secretary from 1817 to 1824. At that time, he proposed several plans for a competition to create an encyclopedia modelled on that of Denis Diderot, but designed to bring together the 'positive ideas' of the period, that is, ideas conceived in their relation to modern science and free from the bonds of traditional theology and metaphysics. Comte's encyclopedic project developed into the famous *Cours de philosophie positive (Course in Positive Philosophy)* (1830-42), a complete system of philosophy in six volumes which aimed to provide the foundations for political and social organization in modern industrial society. Meanwhile, he wrote a series of minor works in social philosophy, which became known as the 'opuscules'. The third, *Plan des travaux scientifiques nécessaires pour réorganiser la société (Plan of the Scientific Operations Necessary for Reorganizing Society)* (1822), which is often called 'the fundamental opuscule', presented the first outline of the concepts which would become central to Comte's positivism - the 'law of three stages' and the classification of the sciences (see §3 below).

While pursuing his intellectual career, Comte earned his living first as a mathematics tutor at the École

Polytechnique, then as admissions examiner at the same school. When he lost the latter job , he was forced in 1848 to seek financial support from his disciples in order to survive. All his life Comte regretted his failure to be appointed a tenured professor; he accused François Arago, among others, of deliberately blocking his academic career. He was also unsuccessful when he requested the creation of chairs at the Collège de France: in 1832 the chair of the General History of the Physical and Mathematical Sciences, and in 1846 the chair of the General History of the Positive Sciences.

Comte always linked his theoretical research to the practical aim of moral, social and political reorganization. He considered this reorganization from the theoretical aspect of political science - 'sociology' or 'positive politics' - and from the practical aspect of the union of the social classes. Moreover, it was for the benefit of the proletarians that he gave public courses in popular astronomy between 1831 and 1848. He considered these lectures the prelude to the reorganization of the intellectual system, which, thanks to the scientific knowledge of society, would finally result in 'a politics finally freed from the arbitrary and the utopian' (Larizza-Lolli 1993: 76). Comte wrote the *Discours sur l'esprit positif (A Discourse on the Positive Spirit)* (1844) as a basic introduction to this reorganization. The *Discours sur l'ensemble du positivisme (A General View of Positivism)*, which appeared in 1848, derived from a similar intention, that of presenting to the workers a synthesized vision of positivist philosophy. From 1847, Comte devoted his lectures to the refutation of communism.

The epistemological foundation of Comte's political project tends to be problematic. For Comte, 'epistemology' involved the history, philosophy and methodologies of the sciences, as well as their basic concepts and theories. His positivist politics is based, on the one hand, on historical and logical law, the law of the three stages (theological, metaphysical and positive stages) and, on the other hand, on an epistemological law: the classification or hierarchy of the sciences, fixed according to the order of their arrival at the positive stage of knowledge (mathematics, astronomy, physics, chemistry, biology, sociology). Thus, as a fundamental epistemological concept, 'positivism' designates an intellectual attitude founded on the practice of rational and experimental scientific methods. At the same time, Comte's scientific positivism is a philosophy of the positive sciences, though initially it is also a philosophy of scientific creativity. Comte allowed certain new sciences that had not yet been fully regularized to be classed as positive: for instance, he confirmed the advance of biology to the level of a positive science. The most advanced of all positive sciences - social physics or sociology - allowed for the transformation of society based on the progress of the sciences.

Under the aegis of his Religion of Humanity, first described in the sixth volume of the *Cours de philosophie positive (The Positive Philosophy)* (1842), Comte articulates his vast political project in the *Système de politique positive (System of Positive Polity)* (1851-4). In this work, he gives his project a social and moral goal, founding it on altruism - a term he originated, according to Emile Littré. Comte's last book was *La Synthèse subjective (Subjective Synthesis)* (1856). Never completed, it re-evaluates the role of the sciences from the perspective of a positivist education. Comte died, probably of stomach cancer, on 5 September 1857.

2 Speculation and action

Following the example of Francis Bacon, who stressed the efficacy of combining knowing (*scire*) and doing (*posse*), Comte held that power is proportionate to knowledge: 'From science, comes foresight; from foresight, comes action' ([1830-42] 1975 I: 45). Even though he clearly separates theory and practice in the scientific study of phenomena, Comte orients his positive philosophy towards a constant interrelationship between speculation and action, while keeping it equidistant between rationalism and empiricism.

The pragmatic aspect of Comte's thought goes back to ideas he first expressed in 1816, while still a student at the École Polytechnique. He affirmed the necessity of pragmatism in a letter of 28 September 1819 to his best friend, Pierre Valat, declaring that he could not conceive of a scientific work that would have no useful goal for humanity. Conversely, he added that political research would have to be intellectually challenging in order to interest him; otherwise, it would have no validity in his eyes. This also explains why he underlined the necessity of basing political studies on a scientific foundation.

On the one hand, Comte was interested in a discipline that would soon be known as 'epistemology'. For him, it encompassed the history and philosophy of the sciences, the various methodologies which they used, fundamental scientific concepts and theories, and what he as well as Bacon called 'primary philosophy', which constituted the

synthesis of the regular means of scientific knowledge and their principal, universally valid results. His epistemological concerns later led Comte to establish a 'Table of the Fifteen Universal Laws' in the fourth volume of the *Système de politique positive* (see §§2, 3 below), settling three groups of universal laws about (1) laws formation, (2) static and dynamic theories of understanding, and (3) movement/existence, action/reaction classification and relation. Yet he never worried about defining 'facts', 'scientific verification' or 'observation'. Nor did the problem of the origin of knowledge concern him. Robert C. Scharff rightly emphasizes Comte's insistence 'that such issues [could] not even be understood as issues without recourse to philosophy's history' (1991: 193).

On the other hand, Comte was very conscious of the political, social and cultural problems posed by the French Revolution. As the third opuscule clearly states, he placed himself politically between 'the people' and 'the kings' (1970a: 57), between the 'retrograde' ideas of the latter and the 'critical' ones of the former; in effect, he had rebelled against the royalism and Catholicism of his parents, but at the same time opposed the destructive spirit of the revolutionaries. Similarly, he did not favour the mixture of the retrograde and critical currents advocated by the 'doctrinaires' such as Pierre Royer-Collard, François Guizot, Charles de Rémusat, and Prosper Duvergier de Hauranne, whom Comte grouped in the 'stationary school' (1970a: 69; 1975 II: 43), characterized by 'organic emptiness'. From 1822, after the fading of the spiritual power of the Church, Comte reproached the French body politic for neglecting to create an organization with analogous power. In spite of French politicians' efforts to recast a temporal power, they had, according to Comte, also failed here. He pointed to the absence of any explicit positive theory as proof of the double failure of French politics.

Before his encyclopedic enterprise was sufficiently developed to become the *Cours de philosophie positive*, Comte, in his role of secretary to Saint-Simon and with his approval, edited some research projects which he called 'Programmes'. One example is the *Programme d'un travail sur les rapports des sciences théoriques avec les sciences d'application (Programme of work on the relations between the pure and applied sciences)*, which he published in 1817. From 1817 to 1820, he began a certain number of preparatory works, which were at least initially encouraged, if not conceived, by Saint-Simon. They would continue after 1820, but in a totally different form.

Just as in the fundamental opuscule of May 1822, Comte resolutely insisted on linking his theoretical work to the practical goal of social reorganization in the *Cours de philosophie positive*, the two *Discours* of 1844 and 1848, the *Système de politique positive* and his last writings. Very early, in fact, he had made a definitive and fundamental observation that the development of human intelligence was closely tied to the history of societies, which he formulated as follows: 'intelligence arrives at a higher stage of development when altruism itself is more developed' (1851: 693). It closely connected the development of intelligence with that of the individual's interest in his or her peers, intelligence and altruism both being clear signs of the progress of humanity.

Comte considered the theoretical discipline of sociology to be concerned with the real nature of humanity, and so he gave a higher status to its method, which was originally objective, defining it instead as 'subjective', that is, as situated beyond objective cosmological observation. The objective method employed in the *Cours de philosophie positive* had permitted the passage from the world to humankind. Now it was necessary to go from humankind to the world; hence the designation of this method as 'subjective', that is, as dependent on the real nature of humankind.

3 Comtean epistemology

Comte's epistemology focused on considering and evaluating the social phenomena that the fundamental sciences recognized as subject matter for a 'positive science' - a science based on observation with a legitimate place in the system of recognized sciences. His epistemology reverses the accepted hierarchy of the sciences - astronomy, physics, chemistry and biology, all of which were traditionally subordinated under mathematics - and places them under the domination of sociology. Comte thought that once the principle of sociality was accepted by scientists, the new science should be called 'anthropology'; he presents this in the *Discours sur l'esprit positif* (1844), where he defines the underlying nature of the scientific approach as necessarily social. First, a 'semiotic principle' justifies it as social, because it originates in the constitution of the different systems of signs produced by society, especially the society of scientists. Second, it is social because it obeys a 'principle of homology' (Kremer-Marietti 1980: 53-69), which applies to all relations and then expresses the possibility of applying the

scientific norm of theoretical unification - a norm that Comte shared with Henri Poincaré. The principle of ‘classification’, which would also be recognized by Pierre Duhem, is justified by the principle of homology; the latter belongs logically to a more general thesis (which Poincaé would later formulate) according to which ‘it is illegitimate to take into consideration a single isolated hypothesis in order to verify it’ (Duhem 1914: 393; Kremer-Marietti 1992: 372). In Comte’s case, it gives rise to the conception of the ‘Table of the Fifteen Universal Laws’; the theoretical unity achieved by Comtean epistemology thanks to this table is due to the organization of all laws through a classification of scientific facts. Comte distrusted a logic isolated from science, a fact isolated from theory, a doctrine isolated from method, and a method isolated from its object. It was necessary to have a theory in order to locate the observations which, if isolated, would have no scientific value. Comte never stopped saying that the ‘crudest’ phenomena explain the ‘noblest’ ones.

Oddly enough, without this holistic type of explanation ordering the homology of the concepts of the world and man, abstract morality could not gain access to the positive system. For Comte, the reference to a system obeying the principle of homology was a universally practicable theoretical necessity - a criterion of verification which he could use to assess the value of experiments and conclusions.

In his ‘Oral Course in Positive Philosophy’, given from 1826, Comte developed his general review of the positive sciences, which he subjected to the historical and logical law of three stages. His teaching plan followed the classification or hierarchy of the sciences, which he saw as a fertile classificatory model. Henceforth he would elevate this model to the status of a key or grid of concepts. Not only did he depend on it to determine, according to the law of three stages, the historical and logical necessity of sociology, a new discipline dealing with social, historical and political points of view, but even more important, this classification permitted him to proceed in certain areas where observation was not yet possible. It is on this principle of classification that Comte established his ‘cerebral theory’ (see §4 below). He also drew the necessity of ‘abstract morality’ (the seventh fundamental science) from his view that the order of the individual, concerned with abstract morality, is at the very heart of sociology, where it is subordinate to the social order, exactly as the social order is subordinate to the vital order and as the latter in its turn is subordinate to the material order. In Comte’s eyes, these successive subordinations do not exclude either the specificity or the originality peculiar to the different orders of phenomena and their respective sciences. The seventh degree of the series of sciences ‘arrives’, according to Comte, ‘at man envisaged in the most precise fashion’. Because the double weight of the material and vital orders is in reality borne by the social order, which helps to modify them, the ‘order of the individual’, the most dependent of all, becomes the ‘immediate regulator of our destinies’ at the same time that it experiences the pressure of all the orders through the social order, to which it is subordinate.

4 The logic of systems and the semiotic principle

Comte highlighted a history of human logics by emphasizing the necessary and reciprocal connection between the systems and institutions of signs, which are languages, and social systems. He saw social history as being affected by the systems of logic which he recognized as existing at three levels: the ‘logic of sentiments’, the ‘logic of images’ and the ‘logic of signs’. This tripartition into sentiments, images and signs contains the semiotic elements that we can recognize in Charles Peirce’s semiotic as Firstness, Secondness and Thirdness (Peirce 1966: 241) (see Peirce, C. §7).

Language appeared as a dynamic system relating political life to domestic life. It allowed for the creation of a positive science whose basis was observation but whose ideal reference was mathematical language, which arose from the logic of signs. Comte’s semiotic position explains his mathematical views. He called attention to the fact that physical science depended as much on observation guided by theory as on the proper use of a model of language, which, to him, was the language of mathematics.

As early as 1819, Comte maintained a general theory of language and signs in his *Essais sur la philosophie des mathématiques (Essays on the Philosophy of Mathematics)*. This logic of the systems of signs in both science and aesthetics was clearly confirmed in 1852 in the second volume of *Système de philosophie positive*. Written long after the first and long before the second of these works, the *Cours de philosophie positive* contains an epistemology concerned with revealing the scientific means of demonstrating the final necessity of the human and social sciences. These sciences are ruled by a logic of systems, of which the law of three stages is the determining operational element.

The ‘positive logic’ of the *Système de philosophie positive* is nothing other than a combination of systems of signs (affective, imaginary and intellectual), subjected to the unification of the three systems governing sentiments, images and linguistic or mathematical symbols. Comte wanted every ‘logic of signs’ to be expressly connected with the ‘logic of images’ and the ‘logic of sentiments’. He reaffirmed the semiotic principle in 1856, in *Synthèse subjective*, and this led to a complete formulation showing how ‘the regular conjuncture of sentiments, images and signs’ was able ‘to inspire in us conceptions that meet our moral, intellectual and physical needs’ (1856: 27).

The logic of the systems of signs arises from ‘the interior function of language’ because, according to Hobbes, people communicate by signs, with one phenomenon becoming the sign of another phenomenon. The Table of the Fifteen Universal Laws may be considered the outcome of this logic. The reason is that this table achieves an intellectual unity through its reduction to a precise and definite number of signs, which are specific laws, valid for all phenomena.

Evidently, there is a link between the three Comtean logics and the three-stage law and an even closer link between these logics and the three sub-states of the theological stage. In fact, Comte thought that fetishism, polytheism and monotheism were at the origin of these three logics, whose development was closely connected with the system of society. The logic of sentiments originated in fetishism, the logic of images was created under polytheism, and the logic of signs (linguistic and mathematic) arose from monotheism. It is clear that this semiotic principle has important implications for Comte’s epistemology as well as for his theory of language and art.

5 The moral and political plan

The opuscules of his youth, appended to the fourth volume of the *Système de philosophie positive*, demonstrate Comte’s constant interest in moral and political reconstruction, in which semiotics played a role. As mentioned above, semiotics was connected with the law of three stages and the three theological sub-states. In Comte’s eyes, fetishism was superior to the other two sub-states because it founded human language. For Comte, the ‘fetishist thinker’ was closer to phenomenal reality than the ‘theologicist dreamer’. Yet the theologians taught us to consider purely ideal existences, without which we would not have been able to create the scientific realm. In addition, without monotheism, abstraction would have been impossible.

It is important to remember that mental states have their ontological foundation in the corresponding social state. It is impossible, for example, to speak abstractly of a society that embraces a specific intellectual and mental state. Thus man and society advance in correlation with the development of intelligence. As a result, the positivist project for society studies the different forms of learning, from the most ancient to the most advanced, by means of knowledge of the various forms of civilization.

The study of ‘social statics’ brings out the principle of solidarity that is crucial for the coexistence and cohesion underlying all social systems. The study of ‘social dynamics’ highlights the principle of the continuity and tradition of societies. In brief, scientific positivism demands that we act so that theory and practice are in harmony. This harmony in turn generates the harmony between the knowledge of the environment that surrounds us and our reaction to this environment.

If knowledge leads to power over the outside world, our industrial society should be able to realize an equitable political project only by developing an all-embracing moral project. If Comte had limited himself to considering the use of abstract science in the ‘sciences of application’, or the results of the latter on industry, the industrial activity arising from positive science would not suffice to constitute a project for society. Because of his familiarity with all scientific areas, Comte turned to a complete knowledge of man; he contended that abstract morality, the ‘final science’, could ‘systematize the special knowledge of our individual nature by combining the biological point of view with the sociological’ (1851-4: 2, 438). To this end, Comte provided the essential epistemological basis with the ‘cerebral chart’, established in 1851 from his method of classification. ‘Abstract morality’ usually precedes ‘concrete morality’; from the ‘cerebral chart’ emerges the principle of man’s action in society: ‘Act out of affection, and think in order to act’ (1851-4: 1, 680-733). The phrenology of Franz Josef Gall, which he criticized for separating the brain from the whole nervous system and detaching the individual from his social milieu, permitted Comte to maintain the innateness of human qualities and the importance of the emotions, as well as the distinction between the mind and the heart: their harmony constitutes the soul. For Comte, the rule of positive society will be love, a basic feature of humanity and thus something which it is possible to expect human

beings to develop.

6 The human sciences and the standard conduct of nations

A fundamental question remains: How does Comte's epistemological system make it possible for him to create a political project?

The analysis of the human psyche (§5 above) showed that the need for love transcends natural egoism by means of altruism. The cerebral chart claimed that both speculation and action are dominated by affection and that social consensus depends on the affective life. Comte, who recognized the permanence of affectivity, expressed it by the phrase, 'One tires of thinking and even acting; one never tires of loving', a progressive division in intermediate items between extreme terms. Using a process of binary decomposition, Comte was able to derive the scale of all the intermediary affections between complete egoism and pure altruism. His analytical method was inherent in the taxonomic method that he usually used. It permitted him to maintain that altruism 'when it is energetic, is always better able than egoism to direct and stimulate the intelligence, even among the animals' (1851-4: 1, 693). The cerebral theory thus represents the fundamental order of our natural make-up and can be applied to social existence.

Social statics deals with the play of the permanent social forces revealed by Comte. What is the material power of Western society? Comte answered that it is 'number' (the proletariat) and 'wealth' (the administrators of capital). What is its intellectual power? It is the aesthetic and scientific spirit (its representatives in society). What about sentiment? Sentiment is concerned with the heart, which is both masculine and feminine, for man and woman share masculine and feminine traits. Even if Comte considers women intellectually inferior to men, he recognizes in them a superiority in terms of sensibility and makes them the guardians of universal morality; yet women remain auxiliary to men. No doubt it was from his romantic love for Clotilde de Vaux, which lasted a year (1845-6), that Comte obtained his experience of the feminine condition. Theoretically, Comte applies an Aristotelian principle governing the different forces of society: the double principle of the separation of functions and the combination of efforts.

Property, family and language are the necessary elements of social statics, which owes its unity to 'religion'. To Comte, religion is a synthesis of 'dogma', which represents the philosophical unity of scientific theories; 'worship', which directs sentiments; and 'regulations', which govern behaviour. Worship and regulations form the subjective domain of love, which is subordinated to the objective realm of philosophical dogma. Social dynamics can be summarized in the law of three stages; it is the permanent substratum of human action. The harmony between the social static and the social dynamic expresses itself in the principle of progress, which is conceived as the development of order. The postulate of harmony is evoked in the perspective of that which governs and rallies, that is, religion, which is destined to 'bind the interior and to link it to the outside'.

The *Cours* deals with the creation of the system of scientific systems as does the *Système de philosophie positive*, which also proposes the new construction of a political synthesis inspired by religion. This completes the human unity to which the synthesis tends through loving, thinking and acting. Religion thus becomes a super-theory of the immediately applicable unity; it permits human intervention in the historical and social dynamic, for it puts morality and politics in the service of social progress. The Religion of Humanity is 'proven' because it is founded on cosmological and human knowledge, and is thus the only answer to moral and political questions. Civil society cannot answer these questions even if its mechanisms permitted it, and it would in any case be unable to set its solutions in motion, since it is nothing but a battleground for divergent opinions. The same criticism is found in the works of Hegel, who limits the civil objective to the satisfaction of needs. While the Hegelian state is called upon to transcend the egoistic civil society by an objective moral idea, Comte wants to orient the will towards the superior reality of humanity, a subjective moral idea. For 'Humanity breaks up first into Cities, then into Families, but never into individuals' (1851-4: 4, 31). Morality takes the individual into consideration; families and homelands are, nevertheless, still important to it as the necessary introduction to Humanity. In terms of its composition, the Great Being is defined as 'the continuous totality of converging beings'.

Comte envisages a future where positive morality determines the discipline of existence. His concept of altruism recalls the principle of friendship or philia, which Aristotle made the cement of the ancient cities. While earlier Comte assigned temporal power to the proletarians, he later entrusts it to those who favoured the 'universal union'.

From 1842, he foresees that the spiritual power has to be 'the true philosophical class'; he therefore gives it the title of 'Western Positive Committee' and already imagines it to be a 'Positive Church'. Comte intends it to direct the intellectual and moral regeneration of modern societies, with the assistance of the proletariat, at least after the latter has ended the transitional dictatorship towards positivism. Just as with all women (who do not form a class), the proletariat is the servant of the spiritual power; it watches over the temporal power to see that it respects the general principles of the social regime.

As for the positive economy, Comte hoped that it would be nothing other than the 'universal and continuous systematization of human toil'. He wanted work to be systematized for the sake of future generations. Capitalization supported the sociocracy, which, according to the evidence of those who recognized its inner workings, involved the collaboration of the social classes based on the model of the functions and organs of the body. (Sociocracy was related to regulation, while sociolatry dealt with worship. Both were founded on sociology, which served as their dogma.) Comte's positivist economic theory was summed up in two laws: first, that each man can produce more than what he consumes, and second, that the products obtained can be preserved beyond the time required for their reproduction. The institution of capital is justified by the preponderance of human work over consumption. Comte's detractors, such as Herbert Marcuse, did not understand his view of the origin and social destination of capital funds. Yet Comte maintained that these capital funds made each active citizen the agent of all the others: each one had to function above all for others by applying the positivist motto 'Live for others'. Others' obligations emanated naturally from the social consensus.

Once the altruistic sentiments were recognized and generalized, Comte thought it possible to treat the three principal obligations - moral, judicial and civic - as one. But there was also an economic obligation to work, and to sustain the products of that work as long as possible; for the importance of solidarity among people would only become clear from the perspective of future generations.

7 The complete positivism

Comte had persuaded his disciples that the active class should nourish the contemplative class. After 1852, thanks to an increase in the Positivist Subsidy, he was able to devote himself entirely to his writings and to represent the priesthood of the Religion of Humanity. He concentrated on asserting the ultimate importance of morality and politics, in this way inaugurating the 'second part of the great revolution'. He affirmed the autonomy of the philosopher as well as that of the positivist movement. Since the appearance in July 1851 of the first volume of the *Système de philosophie positive*, Comte felt that he had completed the philosophical part of his work; he was now free to work on the religious part, which was basically a combination of morality and politics. The *Système de philosophie positive* was to conclude the French Revolution. Comte summed up his solution in the ideas 'Order' and 'Progress', which he combined in a unified and radical way. The positivist mission was to attain not a mixture but a 'necessary harmony' between the retrogression of Comte's time and anarchy. Comte loudly claimed to have answered the needs of the people and satisfied the poor, at the same reassuring the rich. He recommended not intervening in the contemporary political scene, but contented himself with constructing a provisional programme which consisted mainly in the spiritual reorganization of the West, while denouncing the powerlessness and instability of the 'incomplete positivists'.

It was impossible to conceive of an isolated people, far from the great human fraternity. Spiritual unity had to make the totality of human affairs prevail over parties and frontiers. Social positivism (the new religion) had to realize and complete intellectual positivism (the new epistemology). The prestige of progress explained the success that intellectual positivism had obtained. Social positivism would be able to achieve its goals only by reconstructing the spiritual order. As an opponent of theoretical materialism, which privileged the cosmological sciences, Comte believed that it was necessary to ensure the preeminence of the human and social sciences - for him, sociology and abstract morality. In 1856, he called attention to the great trilogy that consisted of his three most important works: *Cours de philosophie positive*, *Système de philosophie positive* and *Synthèse subjective*. According to Comte, the reign of solidarity had arrived - that of individuals and of peoples.

8 Influence

Comte's ideas were initially well received in England after the excellent review of the first two volumes of *Cours de philosophie positive* in the *Edinburgh Review* (1838). Later, John Stuart Mill confirmed his support in *System of*

Logic (1843), in which he presents social statics as the science of the 'coexistences of social phenomena' and social dynamics as that of their progressions. Mill saw in social statics a theory of the consensus between the different parts of the social organization, whereas social dynamics was a theory of society in its progressive movement; their combination led to a law of correspondence between the spontaneous stages and their simultaneous transformations, from which one could then discover the scientific law governing the development of humanity. Like Comte, Mill regarded the speculative faculties of human nature as the agents of social progress, and he also advocated the historical method (his 'Inverse Deductive Method') in the social sciences. In politics, he favoured the separation of powers and the establishment of a consensus based on a common public doctrine. In 1841 he began a six-year correspondence with Comte with an enthusiastic letter, but continued it in opposition to him in three areas: psychology, political economy and feminine intelligence. In *Auguste Comte and Positivism* (1865), Mill categorically rejected the Religion of Humanity, though he still accepted Comte's method.

Alexander Bain, the founder of the journal *Mind*, rallied, if not directly to Comtism, at least to the English positivist school. Like Comte, Bain (1855) connected his psychology to the spontaneous activity of the brain. Similarly, though he explicitly differentiated his own philosophy from that of Comte, Herbert Spencer, who wrote *Social Statics* (1851) on the basis of extreme individualism, then applied the doctrine of evolution to sociology, while at the same time rejecting Comte's conclusions. The English positivist Frederick Harrison, founder of *The Positivist Review*, was also the author of a *Social Statics* (1875). He engaged in a polemic with Spencer to force him to recognize the links between his philosophy and that of Comte. Spencer did at least admit that he owed the concept of social consensus to Comte. Other notable supporters are Richard Congreve (1818-99), who devoted himself to the propagation of English positivism, and Harriet Martineau, who edited a summary of Comte's philosophy, *The Positive Philosophy* (Comte 1830-42).

In France, Comte drew support from certain workers, such as Fabien Magnin, the author of *Études Sociales (Social Studies)* (1913), but his main devotee was the academic Pierre Laffitte, who published numerous positivist texts. Many people who did not strictly adhere to positivism nevertheless came under Comte's influence: Claude Bernard advanced the discipline of experimental medicine and studied the internal environment of advanced living organisms; and Pierre Duhem became well-known for his work on the elements of a natural classification, the epistemological independence of the fundamental sciences, and the holistic thesis. On the other hand, many French thinkers were critical of Comte, notably Émile Meyerson.

In general, Comte's positivism was received in two ways: some absorbed his central themes of the importance of scientific method in resolving social issues but rejected his religious movement; others were deeply impressed by his diagnosis of the crises afflicting modern society and were inspired by his vision for its redemption. In France, the former were led by Émile Littré, who was critical but friendly towards Comte's thought; the latter by Pierre Laffitte, a supporter of the positivist religion and from 1892 Professor of History of Science at the Collège de France. Two positivist reviews were published, *La philosophie positive* (1867-82) under the direction of Littré and G. Wyrouboff, and the *Revue occidentale* (1878-1914) created by Laffitte. The *Revue positiviste internationale* (1906-30) was founded later under the direction of Emile Corra. The religious aspect of Comte's positivism was developed by an English-born American, Henry Edger, who published *The Positivist Calendar* in 1856.

Concepts

The topic of concepts lies at the intersection of semantics and philosophy of mind. A concept is supposed to be a constituent of a thought (or 'proposition') rather in the way that a word is a constituent of a sentence that typically expresses a thought. Indeed, concepts are often thought to be the meanings *of words (and will be designated by enclosing the words for them in brackets: [city] is expressed by 'city' and by 'metropolis'). However, the two topics can diverge: non-linguistic animals may possess concepts, and standard linguistic meanings involve conventions in ways that concepts do not.*

Concepts seem essential to ordinary and scientific psychological explanation, which would be undermined were it not possible for the same concept *to occur in different thought episodes: someone could not even recall something unless the concepts they have now overlap the concepts they had earlier. If a disagreement between people is to be more than 'merely verbal', their words must express the same concepts. And if psychologists are to describe shared patterns of thought across people, they need to advert to shared concepts.*

Concepts also seem essential to categorizing the world, for example, recognizing a cow *and classifying it as a* mammal*. Concepts are also* compositional*: concepts can be combined to form a virtual infinitude of complex categories, in such a way that someone can understand a novel combination, for example, [smallest sub-atomic particle], by understanding its constituents.*

Concepts, however, are not always studied as part of psychology. Some logicians and formal semanticists study the deductive relations among concepts and propositions in abstraction from any mind. Philosophers doing 'philosophical analysis' try to specify the conditions that make something the kind *of thing it is - for example, what it is that makes an act good - an enterprise they take to consist in the analysis of concepts.*

Given these diverse interests, there is considerable disagreement about what exactly a concept is. Psychologists tend to use 'concept' for internal representations*, for example, images, stereotypes, words that may be the vehicles for thought in the mind or brain. Logicians and formal semanticists tend to use it for* sets *of real and possible objects, and* functions *defined over them; and philosophers of mind have variously proposed* properties*,* 'senses'*, inferential* rules *or discrimination* abilities.

A related issue is what it is for someone to possess *a concept. The 'classical view' presumed concepts had 'definitions' known by competent users. For example, grasping [bachelor] seemed to consist in grasping the definition, [adult, unmarried male]. However, if definitions are not to go on forever, there must be* primitive *concepts that are not defined but are grasped in some other way. Empiricism claimed that these definitions were provided by sensory conditions for a concept's application. Thus, [material object] was defined in terms of certain possibilities of sensation.*

The classical view suffers from the fact that few successful definitions have ever been provided. Wittgenstein suggested that concept possession need not consist in knowing a definition, but in appreciating the role of a concept in thought and practice. Moreover, he claimed, a concept need not apply to things by virtue of some closed set of features captured by a definition, but rather by virtue of 'family resemblances' among the things, a suggestion that has given rise in psychology to 'prototype' theories of concepts.

Most traditional approaches to possession conditions have been concerned with the internal *states, especially the beliefs, of the conceptualizer. Quine raised a challenge for such an approach in his doctrine of 'confirmation holism', which stressed that a person's beliefs are fixed by what they find plausible overall. Separating out any particular beliefs as defining a concept seemed to him arbitrary and in conflict with actual practice, where concepts seem shared by people with different beliefs. This led Quine himself to be sceptical about talk of concepts generally, denying that there was* any *principled way to distinguish 'analytic' claims that express definitional claims about a concept from 'synthetic' ones that express merely common beliefs about the things to which a concept applies.*

However, recent philosophers suggest that people share concepts not by virtue of any internal facts, but by virtue of facts about their external (social) environment. For example, people arguably have the concept [water] by virtue of interacting in certain ways with H_2O *and deferring to experts in defining it. This work has given rise to a*

variety of externalist *theories of concepts and semantics generally.*

Many also think, however, that psychology could generalize about people's minds independently of the external contexts they happen to inhabit, and so have proposed 'two-factor theories', according to which there is an internal *component to a concept that may play a role in psychological explanation, as opposed to an* external *component that determines the application of the concept to the world.*

1 Concepts as shareable constituents of thought

Constituents of thought. It is widely thought that 'intentional' explanation in terms of such states as belief, thought and desire affords the best explanation of the behaviour and states of people, many animals and perhaps some machines: someone drinks water because they have a thirst which they think water will quench. By and large, philosophers and psychologists such as Fodor (1975, 1991) or Peacocke (1992) who are interested in intentional explanation take themselves to be committed to the existence of concepts, whereas those sceptical of this form of explanation, for example, Quine (1960), tend to avoid them (see Animal language and thought; Cognitive development; Intentionality).

Suppose one person thinks that water dissolves salt, and another that it does not. Call the thing that they disagree about a 'proposition' - for example, [Water dissolves salt]. It is in some sense shared by them as the object of their disagreement, and it is expressed by the sentence that follows the verb 'thinks that'. Concepts are the constituents of such propositions (in at least one understanding of them; see Propositions, sentences and statements), just as the words 'water', 'dissolves' and 'salt' are constituents of the sentence. Thus, these people could have these beliefs only if they had, *inter alia*, the concepts [water], [dissolves], [salt].

Just which sentential constituents express concepts is a matter of some debate. The central cases that are discussed tend to be the concepts expressed by predicates or general terms, such as 'is water' or '*x* dissolves *y*', terms potentially true of many different individual things. But there are presumably concepts associated with logical words (for example, [not], [some]), as well as with individual things (for example, [Rome], [2]).

Shareability. If we are to make sense of processes of reasoning and communication, and have a basis for generalization in a cognitive psychology, then concepts must be shareable. Consequently, concepts need to be distinguished from the particular ideas, images, sensations that, consciously or unconsciously, pass through people's minds at a particular time. The concept [cat] could not be some individual experience someone has, since in that case no two people could share it and a single person probably could not have the same one twice. Just what kind of shareable object a concept might be is a matter of considerable disagreement among theorists. In much of the psychological literature, where the concern is often with features of actual mental processing, concepts are regarded as mental representations, on such as words or images.

It will be important with respect to this and later proposals to invoke a distinction from the study of language between types and tokens (see Type/token distinction). A linguistic *token*, such as an inscription of 'café' on a door, has a specific spacetime location: one can ask when and where it occurs; whereas a linguistic *type* - the word 'café' - like any 'universal', is an abstract object outside space and time. One can erase a token of the word 'café', but the type word would still exist. Similarly, concepts could be regarded as internal representation types that have individual ideas as their specific tokens. On this view, you and I could share the concept [water] if you and I have tokens of the same representation type in our minds or brains. There is a good deal of discussion in psychology as to whether concepts in this sense are (type) words, phrases, pictures, maps, diagrams or other kinds of representations, for example, 'prototypes' or 'exemplars' (see §7 below; and Smith and Medin (1981); Rips (1995) for reviews of the psychological literature).

But many philosophers take the view that these mental representation types would no more be identical to concepts than are the type words in a natural language. Words in a language are usually individuated syntactically, allowing both spoken and written tokens of a word to be of the same type, and syntactically identical tokens (for example, of 'bank') to be ambiguous, or of different semantic types. Moreover, different syntactic types - for example, 'city', 'metropolis' - can be synonymous, that is, be of the same semantic type. Similarly, one person might express the concept [city] by a mental representation 'city', another by 'metropolis'; still another perhaps by a mental image of bustling boulevards. But, for all that, they might have the same concept [city]: one could believe and another doubt that cities are healthy places to live. Moreover, different people could employ the same

representation to express different concepts: one person might use an image of bustling boulevards to express [city], another to express [pollution]. So, on the standard philosophical reading (which we shall follow here), concepts are to be individuated differently from the representations that express them.

However, although concepts understood in this latter way are arguably also indispensable to psychology, they raise different issues from those concerning representations that standardly interest psychologists. Questions about representations typically involve just the issues that psychologists have tended to investigate: processing time, ease of judgment, susceptibility to errors. If one person represents cities and their relations ‘spatially’, where another represents them by names and descriptions, this may explain differences in how rapidly the two of them can answer questions about cities; but, again, presumably they both still have the concept [city]. Just why they would, what the possession conditions for [city] or any concept might be, is not easy to say (see §5): the point here is that they seem to involve issues different from the issue of identifying a syntactically defined representation.

This difference between the psychologist’s and philosopher’s typical interest is sometimes obscured by ambiguous phrasing. When Kant identifies ‘analytic’ claims (or claims that express the ‘analysis’ of a concept) as those in which one concept is ‘contained in’ another, he glosses this by saying: ‘I have merely to analyse the concept, that is, to become conscious to myself of the manifold which I always think in that concept’ (1781/1787: A7). In our terms, this could be read as a claim about representations, or (presumably what he intended) about the concepts they express. My mental representation of freedom might invariably involve an image of dancing people, but surely neither Kant nor I would want to say that the analysis of my concept of freedom involved dancing. Conversely, there is no reason that a good analysis should serve as a representation in ordinary, rapid reasonings (for example, identifying something as a bird): indeed, vivid images might serve better.

2 Meanings of words

As most of our examples suggest, concepts are presumed to serve as the meanings of linguistic items, underwriting relations of translation, definition, synonymy, antinomy and semantic implication (Katz 1972). Indeed, much work in the semantics of natural languages (see Jackendoff 1987) takes itself to be addressing ‘conceptual structure’. This is partly motivated by Grice’s (1957) proposal to understand linguistic meaning ultimately in terms of the intentions with which speakers produce linguistic tokens: ‘good’ means what it does at least partly because of what users of the word have intended to mean by it; that is, because of the concept they have intended to express (see Meaning and communication; Grice, H.P. §2).

One problem with this role for concepts is that it is by no means clear just what a theory of meaning is supposed to involve. Some of the issues are exactly the issues we are considering here. However, some issues seem peculiar to language: for example, how much of what is understood in the uttering of a sentence is part of its meaning, or semantics, and how much is part of its use, and so an issue of pragmatics? (See Pragmatics.) If I say of someone ‘He is not very good at chess’, is the meaning simply that ‘It is not the case that he is very good’, or ‘He is bad at chess’?

3 Concepts and analysis

Objects of analysis. At least since Plato’s *Euthyphro*, philosophers have been fascinated by a certain sort of question about constitutiveness: in virtue of *what* is something the kind of thing it is - for example, what is ‘essential’ to something’s being good, a piece of knowledge, a free act? Obviously, not just any truth about the target phenomenon will suffice as an answer: to take Plato’s *Euthyphro* example, merely the fact that the gods love the good is no reason to think that that is what makes something good, any more than that all bachelors eat is what makes them bachelors (see Conceptual analysis).

Some philosophers think such questions are answered by natural science. This certainly seems to be true in the case of ‘natural kinds’ such as water or polio, which arguably have ‘real essences’ largely independently of us (see Kripke [1972] 1980; Putnam 1975; Essentialism). But many concepts, such as [magic], [freedom], [soul] may not pick out any real kind of thing at all (much less one studiable by science): in these cases, all that seems shareable by different possessors of the concept is some belief or other. But even in the natural science cases, some conceptual analysis seems to many unavoidable, if only to determine exactly what the science is about (what makes an investigation one about water, or polio, or consciousness; Bealer 1987).

There is a related question that concepts are also sometimes recruited to answer; not a metaphysical question about 'the nature of things', but an epistemological one about how people seem to know a priori (or 'independently of experience') various necessary truths, for example, that there is an infinity of prime numbers or that equiangular triangles are equilateral ones. However, it should be seen as a substantive and controversial hypothesis, to which we will return, whether this epistemological interest should coincide with the above metaphysical one (see A priori; §5 below).

Philosophers have also sometimes hoped that conceptual analysis would help (dis)solve certain philosophical questions about, for example, truth, free will, personal identity, either by clarifying the commitments of the relevant concepts, or by showing that they were somehow defective. A once popular strategy was to show that the application of a concept was not 'verifiable' (§5 below). A more recent strategy is to show that the application of a purported concept would be unintelligible, as in the case of [absolute space] (Peacocke 1992: ch. 8).

Whatever its ultimate philosophical benefits, conceptual analysis does seem to involve the sort of facts that are relevant to the question of concept possession. Returning to our pair of people who represent cites differently: what seems relevant to the question of whether, despite their different representations, they still have the same concept [city] is what sorts of things they believe are essential to being a city; what things they would and would not count as cities (which is not to say that this would be decisive; see §5). This difference can lend an air of unreality to philosophical as opposed to psychological discussions of concepts, depending, as it does, upon difficult questions about what (one would think) is possible in various often very outlandish situations.

Vagueness. One supposed defect of many concepts should be set aside from the start. The belief in constitutive analyses of a concept is often thought to be undermined by the existence of difficult, borderline cases for its application (Wittgenstein 1953: §§66-7; Smith and Medin 1981: 31). Now, it certainly cannot be denied that the world is full of genuine borderline cases: 'Is drizzle rain?', 'Are viruses alive?'. Arguably, the world does not supply determinate answers: all kinds in the world may have vague boundaries, any precise delimitation of which may depend upon human decision. But this does not imply that all applications of concepts are up to human decision, much less that there are no defining essences of the phenomena they pick out. [Unmarried adult male] may be a perfectly good analysis of [bachelor] not only despite hard cases, but because the hard cases for the one correspond exactly to the hard cases for the other. (See Vagueness.)

4 Referential views

One candidate for the common object of people's thoughts has been simply the referents of their representations, that is, the objects in the world picked out by them. Someone might say that two representations express the same concept if and only if they refer to the same thing(s) in the world. Putting aside the difficult problem of explaining 'reference', this seems an appealing suggestion, clearest in the case of (token) proper names such as 'Aristotle' where the name refers to a specific person (see proper names). When we turn to predicates, however, things are not so clear. There are a number of different candidates for what counts as the 'referent' of a predicate and so of the concept it would express: (1) its extension, (2) its intension (as function), and (3) the property that all the (possible) objects satisfying it have in common.

Extensions. The 'extension' is the set of actual objects that satisfy the concept. For example, the extension of [city] might be the set of cities: {Paris, London, Madrid,…}. Russell (1956) proposed an account of 'propositions' according to which they were composed of real objects in the world combined with properties (see also Kaplan 1979). Extensional logicians such as Goodman (1951) and Quine (1960) think that sets of actual objects are all that are needed for serious science: all that needs to be mentioned are actual lions, tigers and quarks. They realize that this suggestion clashes with our ordinary understanding. [Cordate] is not the same as [renate], despite the fact that (let us suppose) all and only actual creatures with kidneys are creatures with hearts ([renate] and [cordate] are 'coextensive'). It seems reasonable to require concepts to cover *possible* cases, for example, possible creatures that are renates but do not have hearts. Goodman would not agree, since, as he famously argues (1951: 5), 'the notion of "possible" cases, of cases that do not exist but might have existed, is far from clear' (see Counterfactual conditionals; Goodman, N. §3). But he and Quine would also be wary of talk of concepts generally; and semanticists such as Kaplan (1979) and Salmon (1986) are anxious to avoid introducing talk of them into talk of the semantics of language.

Intensions as functions. Although one might agree that modal notions such as possibility and necessity are not as clear as one would like, it is by no means agreed that science can actually dispense with them. Many philosophers think that the laws essential to causal explanation in any science require modal and counterfactual talk. But, especially in psychology, it seems doubtful that extensions would perform all the explanatory work concepts are needed to perform. Whether or not biology need worry about the possibility of renates lacking hearts, someone could *think* something is a renate without thinking it has a heart. Consequently, many philosophers have claimed that, in addition to extensions, there must be 'intensions', or entities distinguished more finely than mere extensions permit (see Intensional entities; Intensional logics).

Intensions have been defined in a number of ways. One approach is in terms of 'senses' or 'modes of presentation', to which we shall turn shortly (§5 below). Another approach simply amplifies the extensional characterization to include sets of possible as well as actual objects. Modal logicians and formal semanticists such as Montague (1974), D. Lewis (1972) and Stalnaker (1984), interested in presenting a formal account of the semantics of natural languages, have regarded intensions as functions that map a possible world to the extension of the concept in that world (see Semantics, possible worlds).

However, mere appeals to possibilia may still not cut things finely enough: for there are concepts that are different even though they apply to all the same things in all possible worlds, for example, [equiangular triangle] and [equilateral triangle], or, following Kripke ([1972] 1980), [water] and [H_2O]; or, to take cases of necessarily *empty* extensions, [square circle] and [married bachelor], which both refer to nothing in all possible worlds. Particularly interesting examples of this latter category have been suggested by Kripke ([1972] 1980) and Slote (1975), who argue in different ways that nothing could possibly satisfy the specific demands of [unicorn] or [monster]. How are we to distinguish these concepts by reference to possible objects?

Properties. Some philosophers think the appropriate reference for predicate concepts is not provided by the objects that the concepts pick out (whether in the actual or merely possible worlds), but rather by the properties those objects share. Thus, [city] is not individuated by the set of all actual or possible cities, but rather by the property, 'being a city'.

Historically, concepts have not always been clearly distinguished from properties, both being regarded as 'universals' (see Universals). Thus, the *mortality* one found widespread among men was often assumed to be the same as the concept [mortality] that was a constituent of one's fears. Sometimes this identification seems terminological, as in Frege (1892a) (who uses 'concept' in a quite special way and discusses 'senses' independently), but at other times it is substantive, as in Carnap (1952). Most writers these days would distinguish the two (Putnam 1970; Bealer 1982), even if they also think that there is a property for every concept.

An interesting issue raised by Frege (1892a) that does seem common to both general concepts and properties is the difficulty of specifying exactly what sort of entities they are. As Frege noted, they seem to be incomplete, or 'unsaturated', having places in them awaiting completion by objects, in the way that predicates in language, such as '*x* loves *y*', have variables awaiting substitution with names (such as 'Romeo' and 'Juliet'). This issue becomes important when we try to specify how general and singular concepts combine to form a thought, or how properties and objects combine to constitute facts (Russell 1903: ch. 4; Wittgenstein 1921).

Many worry that appealing to properties to individuate concepts is gratuitous metaphysics, a free invention of a property for every concept, encouraged by the loose presumption that properties, such as 'immortality', can exist even without being instantiated. To answer this charge, philosophers often claim that properties are provided by the actual causal structure of the world: having kidneys and having a heart enter differently into causal relations, as perhaps do equiangularity and equilaterality (Sober 1982). Particularly philosophers of mind such as Dretske (1981, 1988), Millikan (1984) and Fodor (1991), interested in causal interactions between an organism and the world, find this way of thinking about concepts attractive (see Semantics, informational; Semantics, teleological).

However, it is not clear that causal properties will suffice. Are all our concepts really of causally efficacious properties? What about the concept [an inefficacious property]? Or concepts of secondary properties ([red], [sweet]), or ethics and aesthetics ([good], [comical]), which, many have argued, do not pick out genuine causal properties? Or consider, again, necessarily coextensive concepts such as [water] and [H_2O] - which arguably correspond to the same property - or [round square] and [married bachelor], which arguably correspond to none.

How could they differentially enter into the causal structure of the world? Or should we suppose that properties can be distinguished even though they are indistinguishable not only in the actual, but in all possible worlds? Are there any constraints?

Moreover, even if we could distinguish concepts by properties, that would not suffice for conceptual analysis. Plato's *Euthyphro* question - is something good because the gods love it, or do they love it because it is good? - brings this out nicely, since the question remains even if we assume that that gods love the good in all possible worlds (so that [good] and [god-beloved] are necessarily coextensive): the *direction* of analysis still needs to be specified.

5 Possession conditions: external v. internal

Many philosophers might not think that Plato's *Euthyphro* question needs an answer: for purposes of logic, and perhaps even formal semantics, appeal to any of these external phenomena (extensions, intensions or properties) may suffice, 'analysis' be hanged. However, if concepts are to play a role in psychology, then one at least wants to know what sort of relation someone must bear to these external phenomena in order to qualify as a competent user of the concept. This is a question about the possession conditions for a concept to which many have thought analyses are crucial.

In considering possession conditions, special care is needed with the peculiar idiom 'concept of *x*' and the ontology it involves. Psychologists often speak of such things as the child's 'concept of causality'. This could mean the representation the child employs of the concept [causality] that the child shares with adults; or it could mean any of the extension, intension or rule that children associate with the English word 'cause'; or it could mean (as in fact it very often does mean) merely the standard beliefs - what some call the 'conception' - that children associate with the extension, intension: [causality]. Which of these is intended all depends upon what entity one thinks of as the concept and what a mere accompaniment of it. What cannot be seriously intended is the suggestion that a child has a concept [causality] that is both identical to but different from the adults'. (What invites confusion here is the 'of' that implies no relation: just as 'the nation of China' means 'the nation, China', so 'the concept of *x*' often means 'the concept, [*x*]'.)

It might be thought that none of the external identifications of concepts could ever be viable for psychology, since psychology is about what is 'in the mind' (or 'in the head'), not what is in the world external to it (see Jackendoff 1987: 126). This would be an error. We have already seen one way in which it cannot be true: in so far as concepts are shareable, they must be distinguished from individual mental episodes. But still it might be thought that a concept must be a *type* of internally specified mental state, since, after all, surely psychology aims to talk about individual minds, even if it categorizes them in various ways. However, an interest in characterizing what is going on in the mind need not exclude alluding to external objects: the fact that extensions or properties may be external to the head is no reason to think them unsuitable candidates for classifying things that are in the head, just as classifying various words in a book as 'about Vienna' does not prevent those words from existing entirely inside the book.

There have been a variety of external relations that philosophers have proposed that would link internal representations to external phenomena in a way that might constitute concept possession. Influential articles by Kripke ([1972] 1980, 1982), Putnam (1975) and Burge (1979) have given rise to a variety of externalist theories of concepts, which look to such facts as actual causal history (Devitt 1981), various co-variation conditions (Dretske 1981, 1988; Fodor 1991) and evolutionary selection (Millikan 1984; Papineau 1987). However, in so far as they rely on real phenomena in the external world, they are subject to certain limitations that many feel can only be surmounted by appealing to some kind of conditions that are 'in the head'.

Intensions: 'senses'. What argues for the need for some internal condition on concept is the difficulty for any purely external account of capturing psychologically real distinctions. The examples of necessarily unextended concepts, such as [round square], suggest that the mind can somehow make distinctions for which there is no possible external reality. Consequently, many philosophers have argued that, in addition to the referent of a general term, there must also be (following Frege 1892b) its 'sense', or 'mode of presentation' (occasionally 'intension' is used here as well; see Sense and reference). Thus, what really seems to distinguish [equiangular triangles] and [equilateral triangles] is not the actual or possible things to which they refer, but rather the way the

mind conceives them: it is one thing to think of something as (or *qua*) an equilateral triangle, another to think of it *qua* an equiangular triangle (which is why the proof that they are necessarily coextensive is informative). And this obviously helps with the problem of the necessarily coextensive: what distinguishes, for example, [water] and [H_2O] are the different 'ways of thinking', not reflected in any even possible difference in the world. For some (for example, Peacocke 1992) concepts are senses so understood. But, of course, we then need a theory of senses.

6 The classical view and empiricism

One conception of senses is provided by the classical view of concepts. This view has two independent parts that are not always clearly distinguished, one making a claim about the nature of concepts, the other about what is to possess them: (a) concepts have an 'analysis' consisting of conditions that are necessary and sufficient for their satisfaction; and (b) these 'defining' conditions are known to any competent user. An interesting, but problematic, example has been [knowledge], whose analysis was traditionally thought to be [justified true belief], but which has turned out to be far subtler, due to counterexamples raised by philosophers such as Gettier (1963) (see Knowledge, concept of).

The example of [knowledge] brings out an important caveat for the classical view: the proper analysis of a concept need not be readily available to a competent user of it. It was not easy for Athenians to reply to Plato's inquiries about [good], nor for recent philosophers to reply to Gettier. According to a reasonable version of the classical view, a competent user's knowledge of an analysis may be 'tacit' or 'unconscious', rather like the 'knowledge' people have of the grammatical rules of their language, which they seem dependably to obey despite being unable to articulate them (see Evans 1981; Katz 1971; Knowledge, tacit; Unconscious mental states). For Plato, the analyses could only be extracted from someone by a process of 'dialectic', involving consideration of various examples and arguments to a point of 'reflective equilibrium' (Bealer 1987: 322; Jackson and Pettit 1995).

The classical view, however, has always had to face the difficulty of primitive concepts: how are they to be defined? An influential (but not the only possible) answer was provided by seventeenth-century British empiricists, who claimed that all the primitives were sensory. Indeed, the classical view has often been uncritically burdened with this further claim, or, anyway, the claim that all concepts are 'derived from experience'. Locke (1689), Berkeley (1710) and Hume (1739-40) seemed to take this to mean that concepts were somehow composed of introspectible mental items - 'images', 'impressions' - that were ultimately decomposable into basic sensory parts (see Empiricism; Sense-data).

Berkeley ([1710] 1982: 13) noticed a problem with this approach that every generation has had to rediscover: if a concept is a sensory impression, like an image, then how does one distinguish a general concept [triangle] from a more particular one - say, [isosceles triangle] - that would serve in imagining the general one? In any case, images seem quite hopeless for capturing the concepts associated with logical terms (what is the image for negation or for possibility?). Whatever the role of images, concepts and our competence with them involve something more (see Imagery).

Indeed, in addition to images and impressions and other sensory items, a full account of concepts needs to consider issues of logical structure. This is precisely what the logical positivists did, focusing on logically structured propositions and transforming the empiricist claim into their famous 'verifiability theory of meaning': the meaning of a proposition is the means by which it is confirmed or refuted, ultimately by sensory experience; the concept expressed by a predicate is the statement of the (perhaps logically complex) sensory conditions under which people confirm or refute whether something satisfies it (see Meaning and verification). Thus, [acid] might be analysed by reference to tendencies to cause litmus paper to turn red; [belief] by observable behavioural dispositions (see Behaviourism, analytic); [material object] by enduring possibilities of sensation (see phenomenalism).

This once popular position has come under much attack in the last fifty years. Few, if any, successful 'reductions' of ordinary concepts (such as [material object], [cause]) to purely sensory concepts have ever been achieved, and there seems to be a pattern to the failures (Chisholm 1957). There have been four main diagnoses: (1) the classical search for 'necessary and sufficient' conditions is misguided and ought to be replaced by an appreciation of the role of a concept in our reasonings and theories of the world; (2) concepts should be regarded as 'family resemblance' structures, or 'prototypes', (3) because of the 'holism of confirmation', attempts to

analyse concepts in terms of any verification conditions cannot succeed; and (4) we should stop looking for characterizations of concepts in terms of epistemic conditions, but rather, more metaphysically, in terms of the actual phenomena in the world to which people are referring, but about which they might be ignorant (thus, we would abandon clause (b) of the classical view, which requires analyses to be known by competent users). We will discuss each in turn.

7 Inferential roles and prototypes

Inferential roles. The first alternative, inspired by Wittgenstein's famous dictum, 'the meaning of a word is its use' (1953: §43), treats concepts as involving some or other role of a representation, either in a theory or in thought. Thus, many (for example, Kuhn 1962) have argued that someone possesses a concepts such as [witch] or [phlogiston] only if they understand the theories in which they play a role, or can reason with it in certain appropriate ways (see Semantics, conceptual role).

A vexing problem with this approach has been the fact that it is hard to identify just which roles are essential to a concept. It would appear that people can be wrong and/or disagree about almost anything: Berkeley claimed that material objects were ideas, some creationists that people are not animals, some nominalists that numbers are concrete objects. If people are genuinely to disagree with these views, they must share the relevant concepts; otherwise their use of the same words would be equivocal, their disagreement 'merely verbal'. But then it seems very hard to insist upon any specific inferential role being essential to possessing a concept.

Prototypes. Another proposal also inspired by Wittgenstein (1953: §66) is to appeal to 'family resemblances' among the things to which a concept applies: he claimed that games, for example, share no single property, but are similar to each other in various ways that cluster together (some involve winning/losing, others mere entertainment; some are played in groups, others alone). This speculation was taken by psychologists (for example, Rosch 1973; Smith and Medin 1981) to be a testable psychological hypothesis. They showed that people respond differently (in terms of response time and other measures) to questions about whether, for example, penguins rather than robins are birds, in a fashion that suggested that concept membership was a matter not of possessing a classical analysis, but of 'distance' from a 'prototype' or typical 'exemplar'. Thus, a robin satisfies many more of the features of a typical bird than does a penguin and so is a 'better' member of the category; and a malicious lie is a better case of a lie than a well-intentioned one.

It has not always been clear precisely what sort of thing a prototype or exemplar might be. One must take care not to import into the mind procedures, such as comparing one actual bird with another, that make sense only outside of it. Presumably either a prototype or an exemplar is some sort of representation (a list, or an 'image') indicating selected properties, and a metric for determining the distance of a candidate from those properties. Some writers have exploited the resources of 'fuzzy set theory' to capture the intended structure, whereby membership of a category is understood not as an 'all or none' affair, but as a matter of degree: everything satisfies every concept to some degree, however small (see Zadeh 1982; Fuzzy logic).

Quite apart from specifying just what the view involves, there are, however, a number of problems with appeals to prototypicality as a theory of concepts. In the first place, loosening the conditions on a concept's application from 'defining' conditions to mere 'family resemblances' risks leaving that application far too unconstrained. Everything after all bears some resemblance to everything else (Goodman 1970): returning to Wittgenstein's example, anything, *x*, resembles standard games in some way or other (if only in belonging to some arbitrary set that contains all games and that thing *x*!). The question is which resemblances are *essential* to the concept, and which merely *accidental* - a question that returns us to the question the classical view tries to answer (see Essentialism).

Second, prototypes seem poor candidates for handling the crucial phenomenon of conceptual combination: the prototype for [tropical fish] does not seem constructible from the prototypes for [tropical] and [fish], yet someone could grasp [tropical fish] none the less (Osherson and Smith 1982).

Third, prototypicality, which presumably involves distances among a complex cluster of diverse properties, must be distinguished from both vagueness and estimation. As we have already observed (§1), nearly every concept admits of vague cases, in which it is not clear whether the concept applies. But this does not imply that the concept does not have a (correspondingly vague) definition. Similarly, estimation of whether or not something satisfies a

concept is a question that arises with regard to *any* concept. But it is clearly not a *metaphysical* issue of the actual conditions something must satisfy in order to satisfy a concept, but rather an *epistemological* one concerning the belief or epistemic probability that something satisfies the conditions, given certain evidence (see Realism and antirealism). The sight of someone with a toupee may mean that there is a 90 per cent probability that he is actually 50 per cent bald, or a 40 per cent probability that he is actually 95 per cent bald. The question of whether [bald] has a classical analysis is untouched by this issue as well (Rey 1983).

8 Metaphysics v. epistemology

These latter distinctions may turn on the different interests we have already noted (§1) in psychologists' and philosophers' use of 'concept', applying respectively to representations or to their shareable meanings. The fact that people are quicker to say that robins rather than penguins are birds may tell us something about people's representations of [bird], but nothing about the definition of the concept [bird] itself, that is, what is in fact required to satisfy that concept (on reflection, after all, most of us agree that penguins are bona fide birds, despite our initial hesitation). This is not to say that the definitional issue is not relevant to psychology: what people take to be required to be a bird is as much a psychological issue as how they figure out whether those requirements have been met. It is just that prototype theory seems to be addressed largely to the latter issue, the classical view to the former.

However, the differences may be deeper than merely terminological. As the example of estimation shows, it is extremely easy to conflate metaphysical issues about the conditions for something's satisfying a concept with the epistemic ones of estimating whether something actually satisfies those conditions. One reason is that English can encourage running the two together, phrasing the metaphysical question as 'What determines what is what?' and the epistemic one as 'How does someone determine what is what?'. A second reason is that epistemic conditions are as likely to 'come to mind' in thinking with a concept as are its defining conditions (see §1 above).

But a more important reason is that empiricism made a policy of connecting the two: the defining conditions for a concept were to be stated in terms of experiential evidence. As anti-empiricists from Plato on have argued, however, many of our concepts seem to 'transcend experience', in that they seem to be graspable and sometimes applicable in the absence of it. For lack of any genuine Euclidean triangles in the world, it is unclear how our concept of them could be derived from experience. And even instantiated concepts such as [material object], [causation] and [prehistoric] seem to go far beyond mere sensory experience: we seem to be able to think coherently about material objects causally interacting in prehistoric times, even in the absence of any sensory evidence of that interaction. In any case, many of our concepts transcend their stereotypes: most of us understand the concept [female doctor], and recognize that [even number] has a perfectly good definition, despite our demonstrable reliance on stereotypes in both cases (Armstrong, Gleitman and Gleitman 1983).

Moreover, it can often seem arbitrary and unduly restrictive to tie a concept to any particular method of verification (or confirmation). Taking a page from Pierre Duhem (1914), Quine (1953) argued that 'our beliefs confront the tribunal of experience only as a corporate body': litmus paper turning red confirms that a solution is acidic only in conjunction with a great deal of background chemical and physical theory; indeed, Quine claims, only in conjunction with the whole of a person's system of beliefs (a view called 'confirmation holism'; see Analyticity; Confirmation theory; Quine, W.V.). Hence, if a concept is to be analysed as its verification conditions, its meaning would be similarly holistic ('meaning holism'). Given that no two persons' beliefs are likely to be precisely the same, this has the consequence that no two people ever share precisely the same concepts - and no one could, strictly speaking, remember the same thing over any amount of time that included a change of any belief! Fodor and LePore (1992) have recently argued that this sort of conceptual (or semantic) holism would undermine serious psychology, but, fortunately, that the arguments for it are less than compelling (see Holism: mental and semantic; Atomism, ancient).

9 Difficulties for an internalist approach

Even if one distinguishes epistemological from metaphysical issues in determining concept identity, there remain a number of problems for any purely internalist theory of concepts. Whether classical or prototypical, any internalist theory of concepts requires distinguishing internal features - beliefs, inferential roles, prototypes - that are essential to (or defining of) a concept from those that are accidental, and many feel that it really is this distinction that is

undermined by Quine's observations about holism. Indeed, 'sameness of concept' for Quine becomes by and large an 'indeterminate' issue (see Radical translation and radical interpretation). The most one might expect is a similarity of inferential role between symbols in different theories or symbol systems (Harman 1972; Block 1986): which similarities are selected may vary for different explanatory tasks, and may be a pragmatic affair (Bilgrami 1992; Lormand 1996).

A second problem emerged from the externalist approaches of Kripke ([1972] 1980), Putnam (1975) and Burge (1979), and has come to be represented by Putnam's example of 'twin earth' (1975): suppose there were a planet exactly like the earth in every way except that, wherever the earth has H_2O, twin earth has a different, but superficially similar chemical XYZ. Putnam argues that twin-earthlings would not mean by the word 'water' what we mean (for example, their tokens of the sentence 'Water is wet' would not have the same truth-conditions as ours), despite the fact that, *ex hypothesi*, twin-earthlings would have our same internal structure. (Burge (1979) and Stich (1983) present less outlandish examples.) As Putnam famously put it, 'meanings just ain't in the head'; rather, he argues, they depend at least in part upon the relations between internal states and external phenomena (see Content: wide and narrow).

In view of both these examples, and the Quinian worries, Fodor (1991, 1998) opts for an entirely 'atomistic' account of concepts, arguing that concepts have no 'analyses' whatsoever: they are simply ways in which people are directly related to individual properties in their environments, any one of which they might enjoy without the others. In principle, someone might have the concept [bachelor] and no other concepts at all, much less any 'analysis' of it, simply by virtue of having some internal state that is causally connected with bachelorhood in the local environment. Such a view goes hand in hand with Fodor's rejection of not only verificationist, but any empiricist, account of concept learning and construction. Indeed, given the failure of empiricist constructions, Fodor (1975, 1979) argues that concepts are not constructed or 'derived from experience' at all, but are (nearly enough) all innate (see nativism). Devitt (1995) defends a more moderate, 'molecularist' position, allowing that many innate primitives are non-sensory (for example, [cause], [object]) but that others are susceptible to definition, especially in view of the thereby enlarged primitive base.

10 Two-factor theories and a modified classical view

Although externalism does seem to account both for the stability of concepts through variation in belief and for variations in concept due to variations in environment, it still must confront the issues we mentioned earlier (§5) that invite internalism, namely, that there seem to be more distinctions in the mind than are available in the external world. An increasingly popular approach is to separate the internal and external work concepts are asked to perform. According to 'two-factor' theories, 'concepts' should be regarded as having two components: one 'in the head', consisting of an internal representation playing a certain psychological role; and the other, some sort of co-variational law or evolutionary fact that, in a historical context, determines the reference and truth-conditions of the concept. (Sometimes 'concept' is restricted to the internal factor, 'content' to the external; and 'two-factor theory' is sometimes applied only to those views in which the two factors are relatively independent of one another.)

A two-factor theory leaves a place for a modified classical view, as well as for something like philosophical analysis. The internal factor would determine a full semantic content to a conceptual representation only in a particular context, so that the full analysis of (the content of) a concept might await empirical investigation of that context and not be available to its user. But this is perhaps as it should be: philosophical analysis of 'the nature of' a phenomenon may depend both upon the internal rule one is deploying and the actual phenomenon that, in a context, the rule picks out (Bealer 1987; Jackson and Pettit 1995).

Conceptual analysis

A distinction must be made between the philosophical theory of conceptual analysis and the historical philosophical movement of Conceptual Analysis.

The theory of conceptual analysis holds that concepts - general meanings of linguistic predicates - are the fundamental objects of philosophical inquiry, and that insights into conceptual contents are expressed in necessary 'conceptual truths' (analytic propositions). There are two methods for obtaining these truths:

(1) direct a priori definition of concepts;
(2) indirect 'transcendental' argumentation.

The movement of Conceptual Analysis arose at Cambridge during the first half of the twentieth century, and flourished at Oxford and many American departments of philosophy in the 1950s and early 1960s. In the USA its doctrines came under heavy criticism, and its proponents were not able to respond effectively; by the end of the 1970s the movement was widely regarded as defunct. This reversal of fortunes can be traced primarily to the conjunction of several powerful objections: the attack on intensions and on the analytic/synthetic distinction; the paradox of analysis; the 'scientific essentialist' theory of propositions; and the critique of transcendental arguments. Nevertheless a closer examination indicates that each of these objections presupposes a covert appeal to concepts and conceptual truths. In the light of this dissonance between the conventional wisdom of the critics on the one hand, and the implicit commitments of their arguments on the other, there is a manifest need for a careful re-examination of conceptual analysis.

1 Origins and career of Conceptual Analysis

Many of the elements of Conceptual Analysis are present already in John Locke's *Essay Concerning Human Understanding* (1689) - in his doctrines of general ideas and definitions (decompositions of complex general ideas into sets of simple ideas); in his distinction between 'trifling' and 'instructive' universally certain propositions; and in his closely related distinction between 'intuitive' and 'demonstrative' knowledge (see Locke, J. §§3-4). An even more important source of influence is Immanuel Kant's *Critique of Pure Reason* (1781/1787). There Kant makes three crucial sets of distinctions. The first is between 'analytic' and 'synthetic' propositions, that is, between propositions true by virtue of conceptual content alone, and propositions true by virtue of conceptual content together with a non-conceptual semantic element ('intuition'). The second is between a priori (necessary, experience-independent) and a posteriori (contingent, experience-dependent) truths. The third is a threefold division between proofs by empirical methods, 'constructive' proofs in mathematics, and 'transcendental' proofs. Transcendental proofs establish the truth of non-mathematical synthetic a priori propositions by showing how the natural sciences - and human experience itself - presuppose a set of primitive pure concepts or 'categories' (see Kant, I. §4).

Kant's important idea that conceptual truths can be either analytic a priori or synthetic a priori is effectively erased by Gottlob Frege in his *Foundations of Arithmetic* (1884). Frege's overriding philosophical aim is to put mathematical proof on a firm footing by reducing the truths of arithmetic to analytic truths of logic. In view of this, the proper goal of an analysis is the production of non-circular, explanatory, yet meaning-preserving general definitions of fundamental concepts - as exemplified in Frege's famous definition of a number as a class of equinumerous classes (see Logicism; Frege, G. §§7-8). Analytic a priori truths for Frege are propositions that follow deductively either from the self-evident, unprovable laws of pure logic alone, or else from the laws of logic together with logical definitions.

Frege's method was enthusiastically developed and subtly transformed by G.E. Moore in what may be regarded as the first phase of Conceptual Analysis. Moore supplemented Frege's austere logicism with a Kant-inspired attentiveness to the multiplicity of different sorts of concepts, propositions and logico-semantic relations, and with a predilection for arguments resting on appeals to common sense (see Moore, G.E. §§3-4). Moorean analysis then travelled from Cambridge to Oxford, where J.L. Austin and Gilbert Ryle added to it a special focus on the uses and abuses of ordinary language. This led directly to the vigorous growth in the 1950s of the second phase of Conceptual Analysis, sometimes also called 'Oxford Philosophy'. Conceptual analysis was exported to the USA in

the 1950s and early 1960s, primarily through the writings of H.P. Grice and P.F. Strawson. While it found a niche for a time in many American philosophy departments, it did not ultimately survive. It was attacked on several fronts by leading American philosophers (most damagingly, perhaps, by W.V. Quine - see §3 of this entry for details), and by the end of the 1970s had largely succumbed.

2 The theory and methods of conceptual analysis

The career of Conceptual Analysis was rather brief and embattled, but its underlying philosophical theory, conceptual analysis, should be analysed and judged on its own merits. For simplicity's sake, we can think of conceptual analysis as defined by the conjunction of the following five theses:

(1) *The content thesis.* A concept is a general content possessing intrinsic, individuating structures and relations (an intension), and having a corresponding application either to sets of actual or possible objects (an extension), or to other concepts.
(2) *The linguistic thesis.* A concept is the meaning of a predicate-expression; and all such words have meanings only in the context of whole sentences used (first and foremost) in making statements in ordinary discourse.
(3) *The modal thesis.* Every true proposition expressing conceptual interconnections is necessary and analytic.
(4) *The knowledge thesis.* Purely conceptual inquiry produces important a priori knowledge. This knowledge is expressed in analytic propositions known to be true either by (a) direct definitional analysis of conceptual contents, or by (b) indirect 'transcendental' arguments.
(5) *The metaphilosophical thesis.* All fundamental philosophical errors arise from misunderstandings of concepts, and can be corrected only by proper conceptual analyses.

The first two theses convey a theory of concepts. Being general, concepts play the role traditionally assigned to universals (see Universals). Yet because they are ontologically dependent upon ordinary language, concepts are not otherworldly, Platonic entities. And because concept-possession depends upon linguistic use and mastery, concepts are immediately accessible to all competent speakers.

Concepts bear necessary relations to one another and also have fixed internal structures; these relations and structures are open to the process of analysis; and a capacity for analytical insight is guaranteed by linguistic mastery. Concepts, however, are of two quite different sorts: 'categorematic' and 'syncategorematic'. Categorematic concepts (for example, 'bachelor' or 'being taller than') are 'material' intensional contents that uniquely and independently determine concept-extensions. Syncategorematic concepts, by contrast, are 'formal' intensions that apply in a rule-like way to other concepts or conceptual complexes. These in turn are of two sorts:

(1) 'logical concepts' (such as 'conjunction') expressing logical operations; and
(2) 'categorical concepts' (such as 'objecthood') expressing higher-order conditions of the applicability of lower-order concepts.

Analytical insight into categorematic and syncategorematic concepts permits the capture of both non-logical and logical truths (for example, 'bachelors are unmarried males' and '$\sim(P \;\&\; \sim P)$') within the general class of conceptual truths.

The modal thesis tells us that all conceptual truths are analytic and necessary; such truths reflect conceptual contents alone and bear no connections to the disposition of things in the actual world or any possible world. They are therefore 'topic-neutral'. This makes is relatively easy to see why, as the knowledge thesis asserts, the cognition of analytic propositions is a priori: the insight into conceptual content requires no appeal to empirical facts or individuals. And certainly in the case of such simple definitional propositions as 'bachelors are unmarried males', it appears to be the case that a direct awareness of conceptual identity - guaranteed by linguistic competence and the grasp of word-synonymy - requires no appeal to experience in order to be known. But the very idea of a conceptual identity is not so simple as one might think; nor does insight into conceptual truth always result from definitional inquiries alone. This is manifest in three ways.

In the first place, definitional truths do express conceptual identities or synonymies of words, but the criterion of identity cannot be merely that concepts are identical, or words synonymous, when they share the same extensions necessarily. The concepts 'creature with a heart' and 'creature with a kidney', for example, share actual extensions, but are clearly not identical. And as C.I. Lewis first pointed out in 'Modes of Meaning' (1943-4) there

are also concepts - such as ‘equilateral triangle’ and ‘equiangular triangle’ - that are necessarily co-extensional, but not precisely identical. Hence a stricter criterion of conceptual identity, involving an isomorphism of the concepts’ internal structures, must be invoked.

In the second place, there are analytic propositions expressing conceptual relations that reflect only partial identities of concepts, for example: (A) ’bachelors are males’. And most logical truths appear not to reflect *either* complete *or* partial conceptual identities. Here, however, it is possible to appeal to a criterion of analyticity used by Kant, namely that the denial of an analytic proposition leads to a contradiction. This is closely connected with the idea that when terms in partially definitional propositions *are* replaced by their full definitions, or perfect synonyms, logical truths will result. Thus substituting ’unmarried males’ into (A) for ’bachelors’ produces the logical truth, (A*) ’unmarried males are males’. The denial of (A*) is obviously logically contradictory. So an a priori grasp of conceptual identities and logical concepts appears to be sufficient for knowledge of definitional propositions and logical truths alike.

Third, however, there are conceptually true propositions, such as (B) ’nothing can be simultaneously coloured in two different ways all over’ and (C) ’the world as we experience it contains reidentifiable objective particulars in a single spatiotemporal scheme’, that do not seem to reflect logical truths, or even complete or partial identities of concepts, but rather conceptual connections of a somewhat different sort. Here we are strongly reminded of Kant’s view that some conceptual truths are not analytic, but instead synthetic. And indeed, although conceptual analysts generally eschew the existence of the synthetic a priori, this is precisely where the appeal to transcendental arguments comes in. A transcendental argument aims to show that a proposition *P* (say, (B) or (C)) is conceptually true because it is presupposed by another proposition *Q* (say, ’*a* is red; so it is not green’ or ’*a* is not being perceived by me now; but it is still over there just the same’), which is taken by hypothesis to be perfectly acceptable and a ‘paradigm case’ of some class of statements. Not only is *P* a necessary condition of the truth of *Q*, but more profoundly *P* is a necessary condition of the *real possibility* or *meaningfulness* of *Q* - of its being true or false in the first place. This is because the concepts expressed in *P* are categorial concepts having a ’conceptual priority’ over the concepts expressed in *Q*, which is to say that the concepts in *P* have a central place in the overall ’conceptual scheme’ by which language-using human beings organize their common sense experience in the ways exemplified by *Q*. Thus the conceptual truth (B) expresses an insight about the very nature of human experience of colour; and the conceptual truth (C) expresses an insight about the very nature of human perception of objects. Transcendental arguments thus extend the scope of conceptual analysis from the mere definitional or logical exploration of conceptual contents (sometimes also called ’philosophical grammar’), towards insights into first principles expressing the ‘conceptual geography’ of the common sense world (see Transcendental arguments).

The metaphilosophical thesis follows directly from the other four. Concepts govern the ways we think about all things and other concepts; thus not only all philosophical truths, but also all philosophical errors, are conceptual. The two methods of conceptual analysis - definitional and transcendental - must be employed not merely as means of philosophical insight but also for the unmasking and diagnosis of conceptual confusions.

3 Five fundamental objections

The many different lines and styles of criticism directed against conceptual analysis tend to converge on five basic objections:

(1) *The flight from intensions.* If concepts are linguistic intensions, then obviously any sceptical argument showing that intensions do not exist will undermine the linguistic thesis. Just such an argument has been influentially promoted by Quine, in two parts. First, intensions are said to be either ontologically ’mysterious’ or purely psychological entities that intervene between language (or linguistic behaviour) and reference, and should be ruled out of any properly logical and scientific approach to semantic issues. Second, all the explanatory roles traditionally played by intensions - as what words signify, as truth-vehicles, as grounds of synonymy, as grounds of modality, as objects of the propositional attitudes, and as objects of philosophical analysis - can be functionally mimicked by logical or linguistic devices that make no appeals whatsoever to intensional entities (see Intensional entities).
(2) *The death of analyticity.* Perhaps even more famous than Quine’s attack on intensions is his attack, in ‘Two Dogmas of Empiricism’ (1951), on the very idea of analyticity (see Quine, W.V. §8). Setting aside logical truth, Quine argues that non-logical analyticity is based on the concept of synonymy. But every plausible attempt to give

an explanation of synonymy (by appeal to the notions of definition, linguistic interchangeability, or semantical rules) ends either in circularity or vacuity. In the absence of a clear account of synonymy, no clear boundary between analytic and synthetic (factual, contingent) propositions can be established. If sound, this argument forces the rejection of the modal thesis (see Analyticity).
(3) *The paradox of analysis.* In 'Moore's Notion of Analysis' (1942), C.H. Langford points up a deep difficulty in the conception of a definitional analysis. In order for a proposition expressing the results of such an analysis to be correct or true, it must establish a complete or partial identity between concepts. But if an identity is so established, then the very same concept, wholly or in part, redundantly shows up twice in the same conceptual truth, as expressed by two different words or phrases. Thus every correct definitional analysis of a concept is non-informative and trivial; and the very project of definitionally analysing a concept is epistemically pointless. If true, it follows directly from the paradox that the first part of the Knowledge Thesis, which states that all conceptual truths express important a priori knowledge, is false.
(4) *Scientific essentialism and the contingency of conceptual truths.* Enshrined in the linguistic thesis, the modal thesis and the knowledge thesis, are claims to the effect that the meanings of words are conceptual intensions, and that conceptual truths are analytic, a priori and necessary. But it has been influentially argued by Hilary Putnam (1975) that the extensions of some general words - 'natural-kind' terms such as 'water' or 'cats' - are not in fact determined by their corresponding concepts. The extension of a natural-kind word, says Putnam, is instead determined by a strict relation of identity between the natural kind and the microphysical stuff that locally predominates in the samples used by scientists in their empirical investigations (see Reference §3). The stuff's physical microstructure - say, water's being H_2O - is its scientific *essence*; and propositions expressing this essence - say, 'Water is H_2O' - are necessary and a posteriori. But this immediately implies that the conceptual propositions expressed by the use of sentences including natural-kind terms will not be necessary truths. For example, consider the apparently necessary (because analytic by partial definition) proposition 'Water is a liquid'. The natural-kind word 'water' will pick out only whatever stuff in a given world has the microstructure H_2O. But it is possible that on a different world, under different physical conditions, the stuff that is H_2O and a liquid here on Earth might look very different and have very different surface properties: it might be solid, for example. So the conceptual proposition 'Water is a liquid' is false in that possible world; and thus it is only contingently true in the actual world, even if grasped a priori.
(5) *Transcendental arguments presuppose verificationism.* Even supposing that definitional conceptual truths are empty tautologies, and not always necessary, still conceptual truths gained by transcendental arguments would remain cognitively significant and modally secure. But as Barry Stroud (1968) has pointed out, the theory of transcendental arguments assumes a strongly verificationistic theory of meaningfulness for concepts and propositions. Verificationism, however, is afflicted with insurmountable problems. So transcendental arguments are semantically suspect, and the second part of the Knowledge Thesis would thereby seem to be undermined too.

4 The inescapability of conceptual analysis

On the assumption that these criticisms are sound, things look very bleak for conceptual analysis. And it is true that the movement of Conceptual Analysis did eventually break up under the weight of the criticisms just described. But a closer inspection reveals a striking feature of the philosophical dialectic: In order to gain the acceptance of any argument aimed *against* conceptual analysis, it appears that the critic must finally appeal to the truth of some premises that implicitly invoke concepts and conceptual truths.

To take only one central example. Quine's famous arguments against intensions and analyticity all assume the notion of a logical truth. According to Quine in 'Truth by Convention' (1936), a logical truth is a sentence that contains certain words (logical constants) 'essentially': these words preserve their interpretations across every uniform assignment of values to the non-logical constants in the sentence, ensuring that it 'comes out true' no matter what. Now logical constants, with their 'essential occurrence', are semantically equivalent to the conceptual analyst's *logical concepts*; and in this way Quinean logical truths are (covertly) conceptual truths. Moreover, although Quine suggests in 'Two Dogmas of Empiricism' (1951) that even logical truths are revisable, he states in his later *Philosophy of Logic* that 'every logical truth is obvious, actually or potentially' ([1970] 1986: 82), and that the very attempt to deny a logical truth would involve a change of meaning of the logical constants. In other words, logical constants and logical truths are ineliminable parts of any rational conceptual scheme recognizable as

our own. This recognition is epistemically equivalent to what conceptual analysts mean by the a priori grasp of a conceptual truth; the only difference is that whereas most analysts hold that logical truths are known and justified by direct conceptual insight, Quine persuasively appeals instead to a transcendental proof.

If sound, this argument smoothly generalizes. No philosopher can do without logic; and if logic is itself necessarily such as to contain concepts and conceptual truths that are grasped a priori, and whose existence and validity can be established only via transcendental argument, then no philosopher can ultimately avoid the analysis of concepts. Supposing that conceptual analysis is - even in this minimalistic way - philosophically inescapable, the demand for a re-examination and re-working of its basic theses seems self-evident.

Condillac, Etienne Bonnot de (1715-80)

One of the leading figures of the French Enlightenment period, Condillac is the author of three highly influential books, published between 1746 and 1754, in which he attempted to refine and expand the empirical method of inquiry so as to make it applicable to a broader range of studies than hitherto. In the half-century following the publication of Newton's Principia Mathematica *in 1687, intellectual life in Europe had been engaged upon a fierce debate between the partisans of Cartesian physics, who accepted Descartes' principles of metaphysical dualism and God's veracity as the hallmark of scientific truth, and those who accepted Newton's demonstration that the natural order constituted a single system under laws which could be known through painstaking observation and experiment. By the mid-eighteenth century Newton had gained the ascendancy, and it was the guiding inspiration of the French thinkers, known collectively as the* philosophes, *to appropriate the methods by which Newton had achieved his awesome results and apply them across a broader range of inquiries in the hope of attaining a similar expansion of human knowledge. Condillac was at the centre of this campaign.*

Condillac's first book, An Essay on the Origin of Human Knowledge (1746), bears the subtitle A Supplement to Mr. Locke's Essay on the Human Understanding. While Condillac is usually seen as merely a disciple and popularizer of Locke offering little of any genuine originality, and while he did indeed agree with Locke that experience is the sole source of human knowledge, he attempted to improve on Locke by arguing that sensation alone - and not sensation together with reflection - provided the foundation for knowledge. His most famous book, the Treatise on the Sensations (1754) is based upon the thought-experiment of a statue whose senses are activated one by one, beginning with the sense of smell, with the intention of showing how all the higher cognitive faculties of the mind can be shown to derive from the notice the mind takes of the primitive inputs of the sense organs. Condillac also went beyond Locke in his carefully argued claims regarding the extent to which language affects the growth and reliability of knowledge. His Treatise on Systems (1749) offers a detailed critique of how language had beguiled the great seventeenth-century systems-builders like Descartes, Leibniz and Spinoza and led them into erroneous conceptions of the mind and human knowledge, the influence of which conceptions was as insidious as it was difficult to eradicate.

1 Life and historical context

Etienne Bonnot, Abbé de Condillac, was born in Grenoble. His father was a successful lawyer and the family was prosperous. He was educated for the priesthood and took holy orders in 1740. While he remained a priest and was accustomed to wearing the cassock throughout his life, it appears that he celebrated Mass only once and neglected for the most part the other duties which attended his office. Dissatisfied with the education provided for him, he devoted himself to the study of philosophy, immersing himself in the works of Descartes, Malebranche, Leibniz and Spinoza. He read no English, but acquired his knowledge of Locke through the French translation of the *Essay concerning Human Understanding* (1689) by Pierre Coste and read Voltaire's books on Newton. He was the contemporary of such Enlightenment luminaries as Helvetius, Diderot, Buffon, La Mettrie and Holbach. Voltaire and Diderot both expressed the very highest regard for his writings. Condillac was on friendly terms with Rousseau, and was frequently to be seen at the salons in and around Paris where so much of the intellectual activity of the Enlightenment took place. He spent nine years (1758-67) in Italy as tutor to the prince of Parma, and wrote a thirteen-volume course of studies which encompassed history, grammar, poetics and scientific methodology.

The Enlightenment was a period of intense intellectual ferment whose major currents are both multifarious and complex (see Enlightenment, Continental). It is possible nonetheless to isolate several trends and commitments which define more or less the general tendency of thought and the aspirations of those who worked to articulate them. The *philosophes* thought of themselves, perhaps first and foremost, as the champions of the new methods in the natural sciences. They could see important progress being made in so many areas, not only in physics under the aegis of Newton but in chemistry, in navigational technique, in medicine and so on. Their first commitment was to bring the method of the new sciences to bear on as many different lines of inquiry as possible, their guiding assumption being that there was no field of research that could be placed beyond the purview of scientific investigation. But this commitment to the ways of natural science inevitably brought them into conflict with the authority and power of the religious establishment. Though the prestige and political strength of the Catholic

Church had been eroding in France over the first decades of the eighteenth century, it was still a force to be reckoned with, especially where its authority to pronounce on matters of fundamental truth about the world and about the human place within it were challenged. In their attempts to advance the cause of science, the *philosophes* had to contend at every turn with what they called the powers of ‘superstition’ and ‘enthusiasm’, slightly veiled code words for the doctrinal chauvinism of the Church and what to their minds was its reactionary and stultifying influence upon the political institutions and social conditions of the day. These three currents, the defence and advancement of the cause of natural science, the challenge to the traditional authority and power of the Church and a political agenda directed towards the progress of humanity, define what may be taken as the essential thrust of the Enlightenment as an intellectual movement. Condillac’s own contribution to this movement must be set in this context. His philosophy as a whole may be understood as the attempt to hold science and theology together in a single systematic vision of nature, together with a more benign and accommodating perception of man’s place within the natural order.

2 Epistemology

All Condillac’s philosophy begins in the empiricism of John Locke, but he introduces a further methodological component which, he believes, takes him beyond Locke in his treatment of the nature of human knowledge. Disappointed with what appeared to him the idle speculation and dogmatism of the philosophers of the seventeenth century, he writes:

> It seemed to me that we might reason in metaphysics and in morals with as great exactness as in geometry; that we might frame as accurate ideas as the geometricians; that we might determine, as well as they, the meaning of words in a precise and invariable manner; in short that we might prescribe, perhaps better than they have done, a plain and easy order for the attainment of demonstration.
>
> (1746: 2)

Condillac’s epistemology represents the attempt to bring together Locke’s insistence that all knowledge begins with experience with the rigour of a quasi-geometrical method of inference. With Locke, Condillac rejects Descartes’ doctrine of innate ideas, but he wishes to preserve something of the latter’s deductive logic as we move from the simple ideas received through sensation to the more abstract and complex ideas of scientific theory (see Descartes, R.). This attempt to combine elements of Lockean empiricism with Cartesian rationalism is representative of one of the most important aspirations of the Enlightenment thinkers generally. Condillac’s historical importance lies in the fact that he, more than anyone else, tried to work out the details of such a combination with care and precision, and to formulate once and for all the method by which a sure and steady progress could be attained in virtually all areas of human inquiry. It was his hope, and that of all the French thinkers of the time, that the broader application of such a method would yield the same remarkable results in any number of different domains that Newton had achieved in physics through his combination of painstaking observation and mathematical rigour.

Condillac believed that he had made two important advances on Locke by showing, first, how sensation alone, and not sensation and reflection as Locke held, provided all the ideational resources necessary for knowledge and, second, how ‘signs’ or language provided the essential means for moving beyond our personal awareness of our sensations in the direction of objective knowledge. It is for the sake of demonstrating the first of these claims that Condillac constructed the elaborate thought-experiment of the living statue he discusses in his most famous book, the *Treatise on the Sensations* (1754). He asks the reader to imagine a statue whose senses are to be activated one at a time beginning with the sense of smell. His purpose is to show how all the higher cognitive faculties of the mind are generated out of the sequential occurrence of the most primitive of sensory experiences. The statue is presented with the smell of a rose. It immediately discerns the alteration of its ‘mode’ from the utter lack of sensation to the manifestation of the rose’s scent. This awareness of alteration within itself constitutes what Condillac calls ‘attention’, the first and most basic operation of the mind upon the input provided by sensation. The statue is then presented with the scent of jasmine. It attends to the alteration of its own mode and immediately perceives the difference between the rose and the jasmine. This immediate recognition of the difference between the two, and then again the recognition of identity when presented subsequently with the rose, is a manifestation of the mind’s power of judgment. ‘A judgment’, Condillac writes, ‘is only the perception of a relation between two ideas which are compared’, arising from the mind’s implicit capacity to attend to the ideas separately (1754). The

larger significance here is that identity and difference, two notions of fundamental importance for logic itself, are shown to derive from sensation and not to repose in the mind as innate principles or ‘clear and distinct ideas’ available a priori and suited to provide an initiation point for the construction of knowledge.

The statue is able not only to attend to the single presented sensation but to retain an ‘impression’ of the rose while attending to the jasmine. This is memory, which too, according to Condillac, is only a function of sensation. The mind, then, is both passive, in receiving sensations, and active, in making comparisons between sensations present and remembered. With this much of the mind’s capacities described, Condillac asks what might have occurred if the statue had first been presented with an unpleasant smell. If it lacked all experience of pleasant scents, the statue would not, in the presence of the unpleasant one, immediately have experience of anything we could call discomfort or pain, nor would it desire the removal of the unpleasant smell and a return to its former state of utter privation: ‘Suffering can no more make it desire a good it does not know than enjoyment can make it fear an ill it does not know’ (1754: 5). Pleasure and pain, desire and aversion are thus also shown to arise from primitive sensations, but only through the operation of the mind’s capacity for retention, comparison and judgment. Simply put, pleasure and pain are not themselves primitive sensations but learned responses to the mind’s reflection upon the various sensations which come through to conscious experience by way of the organs of sense.

None the less, Condillac claims, no sensations are completely indifferent, as any two of them will inspire within the statue not only a recognition of their difference but also a preference for one over the other. This immediately discernible preference of one sensation over another engenders, over time, the whole vast range of our desires and aversions; with the experience of desire and aversion the primitive capacities of the mind are magnified. On Condillac’s view, our preference for one sensation over another provides a stimulus to the power of attention, enhancing the mind’s ability to focus more keenly and resolutely on ideas stored in memory and leading in turn to a greater discernment and affinity for those sensations which are preferred. ‘If we bear in mind that there are absolutely no indifferent sensations’, Condillac writes, ‘we shall conclude that the different degrees of pleasure and pain are the law by which the germ of all we are is developed, and that they have produced all our faculties’ (1754: 46). Towards the end of the *Treatise* Condillac reaffirms this claim: ‘As without experience there is no knowledge, so without needs there is no experience, and there are no needs without the alternatives of pleasures and pains. Everything then results from the principle which we laid down at the beginning of this work’ (1754: 209).

In the ensuing pages of the *Treatise* Condillac’s statue is endowed, one by one, with the remaining four senses. Condillac attaches special importance to the sense of touch, arguing that it is only with the addition of this inlet of sensory experience that the statue comes to have ideas of space, extension and external objects, and to acquire awareness of itself as something distinct from its own representations of objects.

3 Knowledge and nature as systems

While the *Treatise on the Sensations* is Condillac’s most famous and influential text, it is only in the *Treatise on Systems* (1749) and several less well known works, especially *The Logic* (1780), that Condillac offers his most thoroughgoing exposition of what he conceived of as a system of human knowledge. Having demonstrated the merits of Lockean empiricism in the *Essay on the Origin of Human Knowledge*, he proceeds, in the *Treatise on Systems*, to offer a critical analysis of the rationalistic systems of thought contrived by the great seventeenth-century philosophers, Descartes, Malebranche, Leibniz and Spinoza. Condillac argues that it was their failure to understand the nature and function of language, and the need to derive even the most general and abstract terms from materials provided through sensation, which led these thinkers astray from the very outset of their labours. Much of their deductive method could be preserved, but each link in the chain of inferences must be subjected to linguistic scrutiny to assure that the developing system of concepts allowed in nothing that could not ultimately be shown to derive from sensory experience. ‘The language of philosophy has been nothing else but a gibberish for many centuries past. At length that gibberish has been banished from the sciences’ (1780: 64).

Condillac believed that the language of science might be brought to a clarity and precision analogous to mathematical symbols and equations through what he called the method of analysis. This method requires that we examine each term in our language and try to trace it back to the point at which it connects up with immediate experience. At a simpler, more primitive point in their history, Condillac conjectures, humans were able to make

an apt assignment of 'signs' to those things in our experience which stood out as particularly relevant to our needs and wants. The human capacity for speech is itself a natural endowment neatly insinuated amidst the various other faculties of the mind where it augments and facilitates their operation. 'There is an innate language, though there are no innate ideas' (1780: 56). Nature itself teaches us the method of analysis. So long as we had hitherto comported ourselves in the construction of our language in accordance with its natural tendency, and to the extent today that we come to understand better the ways in which it was originally adapted to our needs and wants, the knowledge we construct on the basis of our growing stock of abstract terms and concepts can be certified as valid and reliable. 'Error begins when nature ceases to inform us of our mistakes; that is, where judging of things which have little relation to the wants of first necessity, we do not know how to try our judgments in order to discover whether they are true or false' (1780: 6).

Condillac's method of analysis can and must be applied in other directions also. Once the basic terms of our scientific vocabulary are correlated accurately and unambiguously with experientially derived ideas, we are able to exercise the power of judgment over the propositions in which they occur in such a way as to extract and formulate with precision the relations and interconnections our linguistic signs implicitly bear to one another. In this way a systematic structure of concepts begins to emerge which in turn enables us to attend more carefully, especially through the use of controlled experiments, to the continued stream of input from sensation. Our knowledge of the world grows through a sequence of inferential steps, and the emergent system of knowledge could be imbued with the same precision and rigour as is to be found in mathematics itself if we would but attend to the clarity and accuracy of our basic terms.

There is much in Condillac which might plausibly be construed as anticipating certain basic themes in the mid-twentieth century movement of Logical positivism. It would be a mistake, however, to impute too great a prescience to Condillac as a precursor of later philosophical movements because there are other, deeply ingrained aspects of his thought which are wholly characteristic of his historical moment and utterly foreign to the later developments. According to Condillac, all human knowledge will ultimately fall together into one vast system of concepts which reflects with perfect accuracy the systematic structure of nature itself. In using the analytic method to trace the meanings of our words back to their origins in sensory experience we are only following out the order in which our ideas themselves were generated in our encounter with nature. The perfect congruence between human knowledge as a system of concepts and nature itself as a systematic whole is ultimately a reflection of the divine intelligence which designed and brought nature into existence. Human nature, and human intelligence as the highest expression of our nature, have been 'conformed' by the creator as an integral part of the natural order and all our needs, desires and cognitive faculties can be brought to reside in perfect harmony with that order. By coming to understand nature as a system we grow in our knowledge of God.

Condillac, in short, was a deist and his philosophy as a whole gives magnificent expression to the eighteenth-century conception of God as cosmic law-giver (see Deism). The laws of nature which Newton had articulated, and all the other laws of nature which science was in process of discovering, were written into the natural order at its inception. But just as nature had its laws, so too there was a set of laws governing human nature, every bit as objective and every bit as amenable to the method of analysis as any other domain of science.

> The faculties and wants of man being given, the laws are given themselves; and though we make them, yet God who created us with such wants and such faculties, is, in truth, our sole legislator. When, therefore we follow these laws which are conformable to our nature, it is Him we obey, and this accomplishes the morality of actions.
>
> (1780: 27)

It was not only human knowledge which could be brought into perfect systematic harmony between all the parts; human conduct too, all of our various personal and social interrelations could be harmonized in accordance with the law of human nature. It was one of the highest aspirations of the Enlightenment period, and of Condillac as one of its philosophically most astute representatives, to raise humankind to the more civilized and prosperous state that would emerge as we gained better knowledge of God's laws, both natural and human. The 'moral sciences' themselves - including the nascent sciences of economics, psychology and politics - could be fully integrated into the whole vast system of natural laws, and to the extent that they were thus integrated and conceived in such a way as to permit a thoroughgoing application of the method of analysis, it was only to be expected that our knowledge

of the human order and hence our ability to secure for ourselves a greater happiness in this world would be enhanced.

4 Reputation and influence

In his own day, Condillac enjoyed a very high reputation in French intellectual circles as the one writer who had devoted his energies to the elaboration of the theory of knowledge required to support the ideals and political agenda of the Enlightenment movement. His works continued to be published in new editions well into the nineteenth century. His philosophy provided the stimulus and inspiration for the early nineteenth-century thinkers known as the *idéologues*, such as Destutt de Tracy and Cabanis. Condillac is often cited in textbooks on the history of psychology as one of the first to bring methodical scrutiny to bear on the subtle dynamics of such cognitive functions as attention, memory and habit formation.

It remains a matter of scholarly controversy whether Condillac really made any important advances over Locke in his treatment of the empirical basis of knowledge. With regard to the two specific points on which Condillac himself believed he had gone beyond Locke, in reducing the source of ideas to sensation alone instead of sensation and reflection and in his theory of language, there is much that could be argued in Locke's defence. Nonetheless, it can hardly be denied that Condillac brought a much greater coherence and clarity to Locke's often tentative and disorganized discussions in the *Essay concerning Human Understanding*. By doing so he is responsible for bringing the empirical spirit of inquiry into a much broader currency on the Continent that it might otherwise have enjoyed. Condillac has not yet been given the careful attention that he deserves, and the full story of how his philosophy has influenced and shaped the later course of the history of ideas has yet to be written.

Condorcet, Marie-Jean-Antoine-Nicolas Caritat de (1743-94)

The Marquis de Condorcet belongs to the second generation of eighteenth-century French philosophes. *He was by training and inclination a mathematician, and his work marks a major stage in the development of what is known today as the social sciences. He was held in high regard by contemporaries for his contributions to probability theory, and he published a number of seminal treatises on the theory and application of probabilism. He is best known today for the Esquisse d'un tableau historique des progrès de l'esprit humain (1795), his monumental, secularized historical analysis of the dynamics of man's progress from the primitive state of nature to modernity.*

Condorcet's principal aim was to establish a science of man that would be as concise and certain in its methods and results as the natural and physical sciences. For Condorcet there could be no true basis to science without the model of mathematics, and there was no branch of human knowledge to which the mathematical approach was not relevant. He called the application of mathematics to human behaviour and organization 'social arithmetic'.

The central epistemological assumption, upon which his philosophy was based, was that the truths of observation, whether in the context of the physical or the moral and social sciences, were nothing more than probabilities, but that their varying degrees of certainty could be measured by means of the calculus of probabilities. Condorcet was thus able, through mathematical logic, to counteract the negative implications of Pyrrhonic scepticism for the notions of truth and progress, the calculus providing not only the link between the different orders of knowledge but also the way out of the Pyrrhonic trap by demonstrating man's capacity and freedom to understand and direct the march of progress in a rationally-ordered way.

In his Esquisse Condorcet set out to record not only the history of man's progress through nine 'epochs', from the presocial state of nature to the societies of modern Europe, but in the tenth 'epoch' of this work he also held out the promise of continuing progress in the future. He saw the gradual emancipation of human society and the achievement of human happiness as the consequence of man having been endowed by nature with the capacity to learn from experience and of the cumulative, beneficial effects of the growth of knowledge and enlightenment. Condorcet's Esquisse laid the basis for the positivism of the nineteenth century, and had a particularly significant impact on the work of Saint-Simon and Auguste Comte.

1 Life

Condorcet was one of the outstanding French mathematicians of his time. He was the only eighteenth-century French *philosophe* of stature to have participated in the Revolution and, as a legislator, to have had an impact on events after 1789. Born in Ribemont, his early education took place at Reims, and by 1758 he had entered the University of Paris where he studied ethics, metaphysics, logic and mathematics at the prestigious Collège de Navarre. There he was taught by the Abbé Nollet, a proponent of Newtonian physics, and he worked closely with Georges Girault de Kéroudon on philosophical matters and on the crucial problems of the integral calculus. In later years he also came under the influence of Euler, Fontaine, the Bernouillis and, above all, of the distinguished mathematician and academician, Jean Le Rond D'Alembert, who became his patron. He was elected Perpetual Secretary of the Academy of Sciences in 1773, and in 1782 became a member of the French Academy. An enthusiastic supporter and theorist of the Revolution, he played an important role in the drafting of the *Déclaration des droits* in 1789. Suspected later of being a Girondin, he was denounced, and died, possibly a suicide, in Bourg-la-Reine while awaiting the guillotine.

His first major work, *Du calcul intégral*, was published in 1765 as part of the Academy of Science's proceedings, and was widely acclaimed. This was followed by a series of essays and mathematical papers, published between 1766 and 1769, including important work on the applications of the integral calculus to the still unresolved mathematical obscurities of Newton's *Principia*. The extensions of the methodology of differential calculus, probability (the 'mathematics of hope') and their application to nonscientific areas, particularly the moral, political and social sciences, were to remain at the core of his thinking, especially during and after Turgot's ministry (1774-6). His exploration of the potential of the calculus of probabilities was developed further in the *Essai sur l'application de l'analyse à la probabilité des décisions rendues à la pluralité des voix* in 1785. The *Essai* is complemented by the *Eléments du calcul des probabilités et son application aux jeux de hasard*, not published in its own right until 1805.

Condorcet was part of that new-wave reformist movement in late eighteenth-century France that included Turgot, the *idéologues*, and the physiocrats, all united in their understanding of how the world of ideas could and must interact with the world of political and social reality. Other major publications include the *Essai sur la constitution et les fonctions des assemblées provinciales* (1788), *Sur l'Instruction publique* (1791-2), *Réflexions sur la jurisprudence criminelle* (1775), *De l'Influence de la Révolution de l'Amérique sur l'Europe* (1786), *Quatres lettres d'un bourgeois de Newh(e)aven á un citoyen de Virginie* (1788), *Lettres sur le commerce des grains* (1775), and the *Réflexions sur l'esclavage des nègres* (1781). In addition, he wrote innumerable pamphlets, drafts of bills and other legislative material for the National Convention. He was also interested in the development of a symbolic logic to give precise expression to intellectual operations and which would be appropriate to the formulation of a universal language of the sciences, although his treatise on this subject, the *Essai d'une langue universelle*, was to remain unfinished. In the non-mathematical area his greatest and most influential work is the *Esquisse d'un tableau historique des progrès de l'esprit humain*, published posthumously in 1795.

2 The science of the probable

Condorcet used mathematics as a model upon which to build a philosophy of social science, and to establish a methodology as applicable to the science of man as it was to the physical sciences. In Condorcet's hands mathematics became an instrument of social and philosophical analysis and, following the lead given by D'Alembert, he set out to integrate the Newtonian view of a rationally determined order of nature into an analagous framework of moral, social and political order. He postulated the view that all human sciences were underpinned by positive fact in the same way as the physical sciences, and open to a rigorous system of analysis made meaningful through the use of a precise, well-determined 'universal' language, capable of unambiguous use across the whole spectrum of scientific enquiry.

Greatly influenced by Locke and Hume, as well as by the French sensationalist philosopher Condillac, Condorcet devoted much of his intellectual life to the development of a concept of 'social arithmetic' based on the calculus of probabilities. He saw probabilism as constituting the essential epistemological link between the social and the physcial sciences. By utilising the calculus of probabilities, the uncertainties and ambivalences inherent in previous attempts to study and evaluate man's behaviour, which had resulted in the case of many philosophers in a profound scepticism, could be dissipated. He was convinced that this 'true philosophy' would provide the foundation for a systematic 'science of man'. The clearest elaboration of this philosophy of probable belief and the methodological principles for its application are to be found in general, tentative outline in the notes to Condorcet's reception speech to the French Academy in 1782, and in more sophisticated mathematical detail in the *Mémoire sur le calcul des probabilités* (1784), in the *Essai sur l'application de l'analyse à la probabilité des décisions rendues à la pluralité des voix* and in the *Eléments du calcul des probabilités et son application aux jeux de hasard*.

In the preliminary discourse to the *Essai sur l'application de l'analyse*, he postulated two key principles governing the processes of human reasoning: (1) that 'nature follows invariable laws' and (2) that these laws 'are made known to us by observable phenomena'. What leads us to believe in the truth of such a postulation is our phenomenological experience of the facts and of the ways in which that experience accords with these two principles. A perfect and definitive calculation of the probability of their truth can never be fully realized, as it is impossible to take cognizance of the totality of the factors that shape our experience. Condorcet insisted, on the other hand, that such a calculation, were it possible, would indicate a very high degree of probability of the truth of these principles. In the light of this probable truth, Condorcet then added a third working proposition, namely that all human reasoning that informs judgment, decision making, choice and conduct is based ultimately on probability.

'The truths proved by experience are simply probabilities.' For Condorcet this insistence on uncertainty did not, however, lead to the *impasse* of Pyrrhonism. On the contrary, although all knowledge was founded only on probabilities, the value, or degree of probability could be determined with relative precision.

Condorcet fully accepted the Lockean view on epistemological modesty. Uncertainty characterized all human understanding (exception being made for the mathematical model itself), but for Condorcet, as for Locke, uncertainty was not an invincible, action-denying absolute. In the *Essai sur l'application de l'analyse* he sought to

demonstrate, by means of the calculus of probabilities, how the defeatist scepticism of the past could be made to give way before the new positivism.

The calculus of probabilities was applicable in theory to all aspects of human life and behaviour, and in demonstrating the logical foundation for this principle Condorcet developed a view of rational belief that owed as much to Hume as to Locke. Belief in both the moral and physical sciences was in his system simply the representation of things as having to exist in a certain way, based on our experience that what has occurred will tend to recur within a frame of constant laws. Belief was not, however, the result of a raw process of reaction to sense impressions. Man obeys an automatic sentiment that leads him to belief, but in order to avoid

judgment and opinion degenerating into prejudice and irrationality, Condorcet took care to distinguish between the *sentiment* of belief and the actual *grounds* for belief. Reason and experience must play their part if man was to be rescued from the illusions of the senses and the fleeting impressions made upon the senses. To this end, he advanced the view that reason had found a powerful weapon in the form of the calculus of probabilities, which offered a dependable methodology for the estimation of the *grounds* for belief. The calculus would provide the necessary mechanism for the correction of any error arising from the passive, automatic and uncritical *sentiment* of belief, particularly important in the case of the moral and social sciences.

The principles of probabilistic philosophy enabled Condorcet to elaborate a model of calculation that permitted the objective evaluation of man in society, and with it he sought to transform the calculus of probabilities into a mathematically-based language of rational decision-making and action. The *Essai sur l'application de l'analyse* was an attempt to illuminate the ways in which the calculus could work in a practical context, in this case the constitutional process itself, so that the unpredictable and the contingent could be measured and minimized. This particular treatise represents Condorcet's most detailed and sustained attempt to 'discover the probability that assures the validity of a law passed by the smallest possible majority, such that one can believe that it is not unjust to subject others to this law and that it is useful for oneself to submit to it'. The mathematics that he then deployed exemplify the pioneering methodology that he would adopt in other contexts, such as crime, jurisprudence and taxation theory, to locate the human sciences within the realm of the probable, and to attempt to address the otherwise intractable problem of accounting for chance in human behaviour.

3 Progress and the science of man

Condorcet's name has been associated most commonly with the 'idea of progress', and the work in which he developed this idea in depth is the *Esquisse d'un tableau historique des progrès de l'esprit humain*. Based on the empirical observation of data and the statistical analysis of that data, the *Esquisse* traces the trajectory of human achievement using a de-christianized chronology of historical periods or 'epochs'. The tableau starts with primitive man in the state of presocial nature and culminates in the ninth 'epoch', covering the years from Descartes and the late seventeenth century to the birth of the first French republic. A tenth 'epoch' offers a vision of the postmillenium future and holds out the promise of unlimited human perfectibility. Condorcet paid particular attention to two factors in man's advancement: (1) the growth of language as the principal vehicle of social progress and intellectual advancement, and (2) the development of technology and the physical sciences as instruments facilitating the progressive liberation of man from the darkness of past error and servitude.

Lockean sensationalist psychology deeply influenced Condorcet, particularly with regard to his doctrine of moral sentiment. At the start of the *Esquisse* primitive man emerges as the one creature with the faculty of receiving sensations, of reflecting upon them, of analysing them and recombining them. In Condorcet's view, the pleasure-pain principle engendered in early man moral feelings, and eventually relationships, based on controlled self-interest. The sensations facilitated man's difficult, but irreversible, climb out the of the darkness of primitive presocial life into the light of civilisation. Condorcet understood the implications for the moral sciences of Lockean reversion to the origins of knowledge in sense experience, together with its consequential destruction of the myth of innate ideas, and he saw Lockean sensationalism as an intellectual event whose importance was matched only by that of the Newtonian revolution in physics.

Condorcet wanted to show in the *Esquisse* that history was not the creation of random forces, with man cast in the role of passive spectator/victim. The gradual emancipation of man from the limitations imposed upon him by nature, and the consequential liberation of the individual, was itself a natural process, and the reflection of an order

inherent in man's condition that could be made intelligible. Man's progress was enacted within the framework of an exclusively human condition, free from the intervention of transcendental forces. Progress was for Condorcet an entirely secular concept, the fruit of human dynamics interacting with the natural currents of history alone. Evil was not a consequence of man's nature but of the absence of enlightenment, and would recede inevitably as knowledge in the moral sciences caught up with the advances being made in the physical sciences, and extended its beneficial effects.

In linking the pursuit of knowledge, and the inexorable logic of scientific advances, to the mission of progress, Condorcet had to demonstrate necessarily that there was a relationship between advances made in the physical and natural sciences and those made in the moral and social sciences, and that as man learned to order his natural environment by means of the physical sciences he would also learn to order his social environment through the advancement of the moral sciences and their political and sociological extensions. The historical portrait of man in the *Esquisse* is drawn with that demonstration in mind in the context of each successive 'epoch'.

Progress for Condorcet was always a cumulative, collective phenomenon, dependent upon the free pursuit of knowledge and upon the rational application of that knowledge. His view of progress assumed that the laws of nature were constant, and that there was an analogous constancy at work in historical processes to which the calculus of probabilities in relation to the future was relevant. A scientific, mathematically-informed study of history would reveal constant principles, many of which would confirm the truth of human progress, as far as this truth could be defined in probabilistic terms.

The power of mathematics allowed man to rise above the facts of random phenomena and to take advantage of the 'law of calculated observations'. This was the law that permitted a scientific understanding of causes, effects and relationships, that allowed for the determination of those recurring patterns of phenomena in human history that made a given truth probable, and that facilitated the measurement of degrees of certainty, and therefore control, in human affairs. It was the key that would open the way to a rationally-planned application of the 'science of man'. The 'science of man', anchored firmly to what were essentially Baconian traditions of thought - observation, experiment, calculation - and Lockean-Humean epistemology, would establish the basis for a radical reordering of the processes of human understanding to create 'a new understanding admitting only precise ideas, exact notions and truths whose degree of certainty or probability has been rigorously weighed'.

Condorcet argued throughout the *Esquisse* the case for the indefinite perfectibility of human society. His vision entailed the construction of a future in which man's potential for social and political choice of action was theoretically infinite. Condorcet's positivism was not facile, however, nor was his optimism Panglossian. The tenth 'epoch' of the *Esquisse*, in some ways naïvely utopian, is a projection of probabilities set out within a cautiously defined context of preconditions, reservations and contingencies. Condorcet never lost sight of the essential fragility of human civilization; progress remained dependent ultimately on the rational exercise of the human will alone, and without that vital driving-force progress would not take place.

Confirmation theory

The result of a test of a general hypothesis can be positive, negative or neutral. The first, qualitative, task of confirmation theory is to explicate these types of test result. However, as soon as one also takes individual hypotheses into consideration, the interest shifts to the second, quantitative, task of confirmation theory: probabilistically evaluating individual and general hypotheses in the light of an increasing number of test results. This immediately suggests conceiving of the confirmation of an hypothesis as increasing its probability due to new evidence.

Rudolf Carnap initiated a research programme in quantitative confirmation theory by designing a continuum of probability systems with plausible probabilistic properties for the hypothesis that the next test result will be of a certain kind. This continuum of inductive systems has guided the search for optimum systems and for systems that take analogy into account.

Carnapian systems, however, assign zero probability to universal hypotheses. Jaakko Hintikka was the first to reconsider the confirmation of such hypotheses and using Carnap's continuum for this purpose has set the stage for a whole spectrum of inductive systems of this type.

1 Qualitative and quantitative confirmation theory

According to the hypothetico-deductive method a theory is tested by examining its implications. The result of an individual test of a general hypothesis stated in observation terms can be positive, negative or neutral. If it is neutral the test was not well devised; if it is negative, the hypothesis, and hence the theory, has been falsified. *Qualitative* confirmation theory primarily aims at further explicating the intuitive notions of neutral and positive test results. Some paradoxical features discovered by Hempel and some queer predicates defined by Goodman show that this is not an easy task.

Assuming that a black raven confirms the hypothesis 'All ravens are black' and that confirmation is not affected by logically equivalent reformulations, Hempel argued (1965) that not only a non-black non-raven but, even more counterintuitively, also a black non-raven confirms it (see Hempel, C.G. §2). Goodman (1955) argued that not all predicates guarantee the 'projectibility' of a universal hypothesis from observed to non-observed cases. For example, if 'grue' means 'green, if examined before *t*' and 'blue, if not examined before *t*', a green emerald discovered before *t* would not only confirm 'All emeralds are green' but also 'All emeralds are grue', and hence, assuming that consequences are also confirmed, even 'All emeralds not examined before *t* are blue' (see Goodman, N. §3). Whereas Goodman succeeded in formulating criteria for acceptable predicates, in terms of their relative 'entrenchment' in previously successfully projected generalizations, up to now nobody has given a generally accepted qualitative solution to Hempel's riddles (see Underdetermination §2).

Below we treat *quantitative*, more specifically, probabilistic confirmation theory, which aims at explicating the idea of confirmation as increasing probability due to new evidence. Carnap introduced this perspective and pointed confirmation theory towards the search for a suitable notion of logical or inductive probability (see Probability, interpretations of §5). Generally speaking, such probabilities combine indifference properties with inductive properties.

2 The continuum of inductive systems

Mainly in his *The Continuum of Inductive Methods* (1952), Rudolf Carnap started a fruitful research programme centering around the famous λ-continuum. The probability systems in this programme can be described in terms of individuals and observation predicates or in terms of trials and observable outcomes. The latter way of presentation will be used here. Moreover, we will presuppose an objective probability process, although the systems to be presented can be applied in other situations as well.

Consider a hidden wheel of fortune. You are told, truthfully, only that it has precisely four coloured segments, BLUE, GREEN, RED, and YELLOW, without further information about the relative size of the segments. So you do not know the objective probabilities. What you subsequently learn are only the outcomes of successive trials. Given the sequence of outcomes e_n of the first *n* trials, your task is to assign reasonable probabilities, $\mathrm{p}(\mathrm{R}/e_n)$,

to the hypothesis that the next trial will result in, for example, RED.

There are several ways of introducing the λ-continuum, but the basic idea behind it is that it reflects gradually learning from experience. In fact, as Zabell (1982) rediscovered, C-systems were anticipated by Johnson. According to Carnap's favourite approach $\mathrm{p}(\mathrm{R}/e_n)$ should depend only on *n* and the number of occurrences of RED thus far, n_{R}. More specifically, it should be a special weighted mean of the observed relative frequency n_{R}/n and the (reasonable) initial probability 1/4. This turns out to leave room for a continuum of (C-)systems, the λ-continuum, $0 < \lambda < \infty$:

$$\mathrm{p}(\mathrm{R}/e) = (n_{\mathrm{R}} + \lambda/4)/(n + \lambda) =$$
$$n/(n + \lambda) \cdot (n_{\mathrm{R}}/n) + \lambda/(n + \lambda) \cdot (1/4)$$

Note that the weights $n/(n + \lambda)$ and $\lambda/(n + \lambda)$ add up to 1 and that the larger the value of λ the slower the first increases at the expense of the second; that is, the slower one is willing to learn from experience.

C-systems have several attractive indifference, confirmation and convergence properties. The most important are these:

(a) order indifference or exchangeability: the resulting prior probability, $\mathrm{p}(e_n)$, for e_n, does not depend on the order of the results of the trials, that is, $\mathrm{p}(\mathrm{R}/e_n) = \mathrm{p}(e_n^*)$ for any permutation e_n^* of e_n;
(b) instantial confirmation: if e_n is followed by RED this is favourable for RED, that is, $\mathrm{p}(\mathrm{R}/e_n\mathrm{R}) > \mathrm{p}(\mathrm{R}/e_n)$;
(c) instantial convergence: $\mathrm{p}(\mathrm{R}/e_n)$ approaches n_{R}/n for increasing *n*.

However, confirmation and convergence of universal hypotheses are excluded in C-systems. The reason is that C-systems in fact assign zero prior probability to all universal generalizations, for instance to the hypothesis that all results will be RED. Of course, this is desirable in the described situation, but if you were told only that there are *at most* four coloured segments, you would like to leave room for this possibility.

3 Optimum inductive systems

Carnap proved that for certain kinds of objective probability process, such as a wheel of fortune, there is an optimal value of λ, depending on the objective probabilities, in the sense that the average mistake may be expected to be lowest for this value. Surprisingly, this optimal value is independent of *n*. Of course, in actual research, where we do not know the objective probabilities, this optimal value cannot be calculated. Carnap did not raise the question of a reasonable estimate of the optimal value for a specific objective process, for he saw the problem of selecting a value of λ primarily as a choice that each scientist had to make in general. However, the question of a reasonable estimate has attracted the attention of other researchers.

Festa (1993) proposed basing the estimate on 'contextual' knowledge of similar processes in nature. For example, in ecology one may know the relative frequencies of certain species in different habitats before one starts the investigation of a new habitat. For a quite general class of systems, Festa formulates a solution to the estimation problem that relates the research area of confirmation theory to that of truth approximation: the optimum solution may be expected to be the most efficient way of approaching the objective or true probabilities.

Unfortunately, wheels of fortune do not constitute a technological (let alone a biological) kind for which you can use information about previously investigated instances. But if you had knowledge of a random sample of all existing wheels of fortune, Festa's approach would work on the average for a new, randomly drawn, one.

4 Inductive analogy by similarity

Carnap struggled with the question of how to include analogy considerations into inductive probabilities. His important distinction between two kinds of analogy - by similarity and by proximity - was posthumously published (Carnap 1980). Here we will consider only the first kind.

Suppose you find GREEN more similar to BLUE than to RED. Carnap's intuition of analogy by similarity is that, for instance, the posterior probability of GREEN should be higher if, other things being equal, some occurrences of RED are replaced by occurrences of BLUE. The background intuition, not valid for artificial wheels of fortune, is that similarity in one respect (for example, colour) will go together with similarities in other respects (for

example, objective probabilities). However, explicating which precise principle of analogy one wants to fulfil has turned out to be very difficult.

One interesting approach is in terms of *virtual trials*, which is a way of determining how analogy influence is to be distributed after n trials. In the case above, BLUE would get more analogy credits than RED from an occurrence of GREEN. The resulting systems of virtual analogy have the same confirmation and convergence properties as C-systems. Moreover, they satisfy a principle of analogy that is in general more plausible than Carnap's. Roughly, the new principle says that replacement of a previous occurrence of BLUE by GREEN makes less difference for the probability that the next trial will be BLUE than does replacement of a previous occurrence of RED by GREEN for the probability that the next trial will be RED.

Unfortunately, systems of virtual analogy are not exchangeable: the order of results makes a difference. There are, however, exchangeable systems with some kind of analogy by similarity. For example, Skyrms (1993) has sketched a Bayesian approach that uses information about possible gravitational bias of a symmetric wheel of fortune to determine the influence of analogy, and di Maio (1995) follows a suggestion of Carnap.

5 Universal generalizations

Carnap was well aware that C-systems do not leave room for non-analytic universal generalizations. In fact, all systems presented thus far have this problem. Although tolerant of other views, Carnap himself was inclined to downplay the theoretical importance of universal statements.

Hintikka (1966) took up the problem of universal statements. His basic idea was to apply Bayesian conditionalization to Carnap's C-systems with uniform λ, using a specific prior distribution on universal statements containing a parameter α. The systems belonging to the resulting α-λ-continuum have the instantial confirmation and convergence properties and also the desired property of universal confirmation; that is, that the probability of a not yet falsified universal statement increases with another instance of it. Moreover, they satisfy universal convergence: $\mathrm{p}(\mathrm{H_R}/e_n)$ approaches 1 for increasing *n* as long as only RED continues to occur (where $\mathrm{H_R}$ indicates the universal statement that only RED will occur in the long run). For increasing parameter α, universal confirmation is smaller and universal convergence slower.

In fact, systems based on an arbitrary prior distribution and C-systems with arbitrary λ, here called H-systems, already have the general properties of instantial and universal confirmation and convergence. The subclass of H-systems based on an arbitrary prior distribution and C-systems with λ proportional to the corresponding number of possible outcomes is particularly interesting. For this subclass appears to be co-extensive with a class of systems introduced by Hintikka and by Niiniluoto (1988), very differently from H-systems, using principles and parameters related only to finite sequences of outcomes.

There is also a plausible 'delabelled' reformulation of H-systems that can be extended to the very interesting case of an unknown denumerable number of possible outcomes. Presenting the delabelling in terms of exchangeable partitions, Zabell (1996) has studied this case by principles leading to a class of systems with three parameters.

6 Applications

The Carnap-Hintikka programme in confirmation theory, also called inductive probability theory, has applications in several directions. Systems of inductive probability were intended primarily for explicating confirmation as increasing probability. One may even define a quantitative degree of confirmation: namely, as the difference or ratio of the posterior and the initial or prior probability. There are other interesting types of application as well. Carnap (1971) and Stegmüller (1973) stressed that they can be used in decision making, and Skyrms (1991) applies them in game theory (see Decision and game theory). Costantini *et al*. (1982) use them in a rational reconstruction of elementary particle statistics. Festa suggests several areas of empirical science where optimum inductive systems can be used. Finally, for universal hypotheses, Hintikka, Hilpinen (1968) and Pietarinen (1972) use systems of inductive probability to formulate rules of acceptance and Niiniluoto uses these systems to estimate degrees of verisimilitude.

Confucian philosophy, Chinese

Chinese Confucian philosophy is primarily a set of ethical ideas oriented toward practice. Characteristically, it stresses the traditional boundaries of ethical responsibility and dao*, or the ideal of the good human life as a whole. It may be characterized as an ethics of virtue in the light of its conception of* dao *and* de *(virtue). Comprising the conceptial framework of Confucian ethics are notions of basic virtues such as* ren *(benevolence),* yi *(rightness, righteousness), and* li *(rites, propriety). There are also notions of dependent virtues such as filiality, loyalty, respectfulness and integrity. Basic virtues are considered fundamental, leading or action-guiding, cardinal and the most comprehensive. In the classic Confucian sense,* ren *pertains to affectionate concern for the well-being of fellows in one's community. Notably,* ren *is often used in an extended sense by major Song and Ming Confucians as interchangeable with dao for the ideal of the universe as a moral community.* Yi *pertains to the sense of rightness, especially exercised in coping with changing circumstances of human life, those situations that fall outside the scope of* li. Li *focuses on rules of proper conduct, which have three functions: delimiting, supportive and ennobling. That is, the* li *define the boundaries of proper behaviour, provide opportunities for satisfying desires of moral agents within these boundaries, and encourage the development of noble characters which markedly embody cultural refinement and communal concerns. The* li *are the depository of insights of the Confucian tradition as a living ethical tradition. This tradition is subject to changing interpretation governed by the exercise of* quan *or the weighing of circumstances informed by the sense of rightness (*yi*).*

However, the common Confucian appeal to historical events and paradigmatic individuals is criticized because of lack of understanding of the ethical uses of such a historical appeal. The pedagogical use stresses the study of the classics in terms of the standards of ren, yi *and* li. *Learning, however, is not a mere acquisition of knowledge, but requires understanding and insight. Also, the companion study of paradigmatic individuals is important, not only because they point to models of emulation but also because they are, so to speak, exemplary personifications of the spirits of* ren, yi *and* li. *Moreover, they also function as reminders of moral learning and conduct that appeal especially to what is deemed in the real interest of the learner. The rhetorical use of the historical appeal is basically an appeal to plausible presumptions, or shared beliefs and trustworthiness. These presumptions are subject to further challenge, but they can be accepted as starting points in discourse. The elucidative use of historical appeal purports to clarify the relevance of the past for the present. Perhaps most important for argumentative discourse is the evaluative function of historical appeal. It focuses our knowledge and understanding of our present problematic situations as a basis for exerting the unexamined claims based on the past as a guidance for the present. Thus, both the elucidative and evaluative uses of historical appeal are critical and attentive to evidential grounding of ethical claims.*

*Because of its primary ethical orientation and its influence on traditional Chinese life and thought, Confucianism occupies a pre-eminent place in the history of Chinese philosophy. The core of Confucian thought lies in the teachings of Confucius (551-479 BC) contained in the Analects (*Lunyu*), along with the brilliant and divergent contributions of Mencius (372?-289 BC) and Xunzi (*fl. *298-238 BC), as well as the Daxue (Great Learning) and the Zhongyong (Doctrine of the Mean), originally chapters in the Liji (Book of Rites). Significant and original developments, particularly along a quasi-metaphysical route, are to be found in the works of Zhou Dunyi (1017-73), Zhang Zai (1020-77), Cheng Hao (1032-85), Cheng Yi (1033-1107), Zhu Xi (1130-1200), Lu Xiangshan (1139-93), and Wang Yangming (1472-1529). Li Gou (1009-59), Wang Fuzhi (1619-92), and Dai Zhen (1723-77) have also made noteworthy contributions to the critical development of Confucian philosophy. In the twentieth century, the revitalization and transformation of Confucian philosophy has taken a new turn in response to Western philosophical traditions. Important advances have been made by Feng Youlan, Tang Junyi, Thomé H. Fang, and Mou Zongsan. Most of the recent works in critical reconstruction are marked by a self-conscious concern with analytic methodology and the relevance of existentialism, phenomenology, and hermeneutics. Still lacking is a comprehensive and systematic Confucian theory informed by both the history and the problems of Western philosophy.*

1 The conceptual framework

A student or scholar of moral philosophy, approaching the classical core of Confucian ethics for the first time, is likely to be faced with a major difficulty in the lack of systematic exposition of basic Confucian notions such as

ren (benevolence), *li* (rites), and *yi* (rightness), and their interconnection. Unlike major Western philosophers, Confucian thinkers are not concerned with definitions. As William Theodore de Bary (1970: v) has pointed out, most Chinese thinkers are not interested in the definition and analysis of concepts: 'generally, the more crucial or central the idea, the greater the ambiguity'. Instead, they are concerned with the expansive uses of ideas that suggest the widest possible range of meaning.

From the point of view of contemporary moral philosophy, this pervasive feature of Confucian discourses may appear to be an anomaly, given the classical emphasis on the right use of terms (*zhengming*). A serious student of the works of Xunzi, the one classical Confucian generally considered to be the most rationalistic and systematic philosopher, will be frustrated in the attempt to find definitions, in the sense of necessary and sufficient conditions, for the application of basic Confucian terms. This fact is all the more surprising in view of Xunzi's recurrent employment of certain definitional locutions or quasi-definitional formulas for explaining his theses on human nature and the mind. Like most major Confucians, Xunzi has a pragmatic attitude toward the use of language, that is, the uses of terms that require explanation are those that are liable to misunderstanding in the context of particular discourse. The Confucian explanations of the use of ethical terms are context-dependent and are addressed to a particular rather than universal audience.

Two different assumptions underlying this attitude toward language may account for the absence of Chinese interest in context-independent explanation of the use of ethical terms. First, there is an assumption of the primacy of practice implicit in the Confucian doctrine of the unity of knowledge and action (*zhixing heyi*). Definition, in the sense of meaning explanation, is a matter of practical rather than theoretical necessity. This assumption does not depreciate the importance of theoretical inquiry, but rather focuses on its relevance to the requirements of practice, particularly those that promote unity and harmony among people in the community. Such requirements vary in time and place. A viable ethical theory is thus subject to pragmatic assessment in the light of changing circumstances. In general, ethical requirements cannot be stated in terms of absolute or fixed principles or rules. It is this assumption of the primacy of practice that renders plausible Donald Munro's claim that the consideration important to the Chinese is the behavioural implications of the belief or proposition in question (Munro 1969). What effect does adherence to the belief have on people? What implications for social action can be drawn from the statement? In Confucianism, there was no thought of 'knowing' that did not entail some consequence for action.

Related to the primacy of practice is the assumption that reasoned discourse may legitimately appeal to what Nicholas Rescher calls 'plausible presumptions,' that is, an appeal to shared knowledge, belief or experience, as well as to established or operative standards of discourse (Rescher 1977: 38). For Confucian thinkers, most of these presumptions, at least among the well-educated, represent the shared understanding of a common tradition and a living cultural heritage. These presumptions are often suppressed and mainly form the background of discourse. Thus Confucian reasoning and argumentation appears to be highly vague and inexplicit. From the Aristotelian point of view, Confucian reasoning is 'rhetorical', as it frequently involves enthymemes and arguments from examples.

Given the assumptions of the primacy of practice and appeal to plausible presumptions, any attempt at introducing Confucian ethics to students of Western philosophy involves a basic task in philosophical reconstruction. This is a task in constructive interpretation, not only in providing a general characterization but also in reshaping the basic notions and concerns of Confucian ethics in response to some problems of moral philosophy. Such an exploration serves two important and connected aims: first, a plausible explication of the Confucian outlook in philosophically relevant idioms, and second, a critical development of Confucian ethical thought.

2 An ethics of virtue: *dao* and *de*

While major Confucianists (for example, Mencius and Xunzi) differ in their conceptions of human nature in relation to conduct, most of them accept Confucius' ideal of a well-ordered society based on good government (see Xing; Mencius; Xunzi). Good government is responsive to the basic needs of the people, to issues of wise management of natural resources and to just distribution of burdens and benefits. In this vision of socio-political order, special emphasis is put on harmonious human relationships (*lun*) in accord with *de*, virtues or standards of excellence. This vision is often called *dao*, a term that has been appropriated by different classical schools of Chinese thought, including Daoism and Legalism (see Legalist philosophy, Chinese; Daoist Philosophy). In the

Analects, *dao* is sometimes used as a verb, meaning 'to guide'; sometimes it is used as a concrete noun, meaning literally 'road'. In the latter sense, it can be rendered as 'way'. But in distinct Confucian ethical usage, as commonly acknowledged by commentators, it is *dao* as an abstract noun that is meant, and more especially in the evaluative rather than descriptive sense, that is, as referring to the ethical ideal of a good human life as a whole (see Dao).

Throughout its long history, Confucianism has stressed character formation or personal cultivation of virtues (*de*) (see De). Thus it seems appropriate to characterize Confucian ethics as an ethics of virtue, not an ethics of rules or principles. To avoid misunderstanding, two explanations are in order. In the first place, the Confucian focus on the centrality of virtues assumes that the notion of *de* can be rendered as 'virtue'. In the second place, this focus does not depreciate the importance of rule-governed conduct (see Moral development).

Sinologists differ in their interpretation of the Confucian use of *de*. Some insist that *de* should be construed as 'power', 'force' or 'potency', and in Confucian usage it should be qualified as moral in contrast to physical force. Others argue for 'virtue' in the distinctively ethical sense, as pertaining to the excellence of a character trait or disposition. Interestingly, these two construals of *de* are not incompatible in the light of some English uses of 'virtue' (see Virtue ethics). In *Webster's Third New International Dictionary*, for example, the sixth definition of 'virtue' is: 'an active quality or power whether of physical or of moral nature; the capacity or power adequate to the production of a given effect', and the fifth definition is: 'a characteristic, quality, or trait known or felt to be excellent'. The *Oxford English Dictionary* likewise offers as definitions 'a good quality' and 'efficacy; inherent power'. Both these senses of 'virtue' are found in the classical Chinese uses of *de*.

There is, of course, the value-neutral sense of *de* that leaves open the question whether personal traits or qualities merit ethical approval, and this question is reflected in the distinction, still current in Modern Chinese, between *meide* and *ede*. The former pertains to 'beautiful' or 'commendable' *de*, and the latter to its contrary. *Meide* are those traits that are acquired through personal cultivation. The *Encyclopedia Dictionary of the Chinese Language* offers the following two entries for *de* in the ethical sense, one suggested by an interpretation of its homophone, meaning 'to get' or 'to obtain', found in the *Liji (Book of Rites)*: 'that which is obtained in the heart-and-mind as a result of personal cultivation', and 'the nature that is formed after successful personal cultivation'. Both these definitions involve *meide*, commendable, acquired qualities or traits of character, much in the sense of David Hume's 'personal merits' (see Hume, D.) *Ede*, on the other hand, are personal demerits or 'detestable' qualities of character.

Also important is the sense of *de* as power or force, in view of the Confucian notion of *junzi* (ethically superior or paradigmatic individuals). By virtue of ethical achievement, a *junzi* possesses the power of attraction or influence indicative of effective agency (see Moral agents). As Confucius remarks, the *junzi*, equipped with the virtues (*de*), never stands alone: 'He is bound to have neighbours.' 'The virtue (*de*) of the gentleman (*junzi*) is like the wind; the virtue (*de*) of the small man is like grass. Let the wind blow over the grass and it is sure to bend' (*Analects* 12.19, in Lau 1979: 115-16). In sum, the Confucian notion of *de* can be properly construed as ethical virtues that possess a dual aspect: an achieved condition of a person through self-cultivation of commendable character traits in accordance with the ideal *dao*, and a condition that is deemed to have the peculiar potency or power of efficacy in influencing the course of human life. The difficult problem is to present the Confucian *dao* and *de* as an ethics of virtue with a coherent conceptual scheme.

3 Basic notions and the problem of conceptual unity

The *Analects*, a composite work, is commonly considered the main and most reliable source of Confucius' teachings (see Confucius). It bequeaths to the Chinese tradition a large and complex ethical vocabulary, which contains a significant number of virtue (*de*) terms with implicit reference to the Confucian ideal of *dao*. Terms such as *ren* (benevolence), *yi* (rightness) and *li* (rites) seem to occupy a central position both in the *Analects* and throughout the history of Confucian discourse. Until recent times, however, few philosophical scholars of Confucianism attended to the problem of conceptual explication and the unity of these basic notions, that is, their presumed interconnection or interdependence in the light of *dao* as an ideal, unifying perspective. While most Confucian terms for particular virtues can be rendered into English without the need of elaborate explanation - for example, *xiao* (filiality), *yong* (courage), *wei* (dignity), *zhong* (fidelity), *ci* (kindness), *jing* (respectfulness) - the apparently basic notions (*ren*, *li* and *yi*) are not amenable to the simple expedience of translation and thus pose a

problem for conceptual analysis and interpretation. Moreover, existing translations of these terms ineluctably embody the writer’s interpretation, a sort of implicit commentary, representing the writer’s prior understanding of the translated texts.

Similarly, an explication of basic Confucian notions involves philosophical commentary, a familiar feature in the development of the history of Chinese thought. However, attempts at explication have been beset by a formidable difficulty, especially in defining the basic concepts of the Confucian framework. The pioneering study of the conceptual aspect of Confucian ethics is Chen Daqi’s *Kongzi xueshuo (Teachings of Confucius)* (Chen 1976). Chen reminds us that prior to interpreting the ideas of Confucius, it is essential to inquire into the conceptual status of some recurrent terms in the text. For determining the centrality or basic status of notions or concepts, Chen proposes four criteria, according to which basic concepts are (1) fundamental, (2) leading or guiding, (3) the most important (cardinal) or (4) the most comprehensive.

Fundamental concepts suggest the distinction between basic and derivative concepts. However, it is more plausible and accords better with Chen’s discussion to construe his distinction as one between basic and dependent concepts. Given our characterization of Confucian ethics as an ethics of virtues, this is a conceptual distinction between basic and dependent virtues. A concept may depend on another for its ethical significance without being a logical derivation. For instance, one cannot derive the concept of love from *ren*, yet its ethical significance depends on its connection with *ren*. This is perhaps the principal ground for Zhu Xi’s famous contention that *ren* cannot be equated with love, for it is the rationale of love (*ai zhi li*) (see Zhu Xi).

Leading or guiding concepts recall the purport of ethical terms as guides for action, informing the Confucian agent that the enduring significance of ethical endeavours lies in the pursuit of *dao* or the ideal of the good human life as a whole. *Cardinal concepts* and *comprehensive concepts* are the chief mark of basic ethical concepts. Comprehensive concepts also raise an issue in Confucian scholarship. Perhaps the issue can be settled if comprehensiveness is ascribed to *dao* or *ren* in the broad sense as signifying the holistic, ideal unifying perspective of Confucian discourse. Again, consider Zhu Xi’s thesis that *ren* (in the broad sense) embraces the four: *ren* (in the narrow sense), *yi* (rightness), *li* (rites) and *zhi* (wisdom). In terms of an ethics of virtue, the fundamental distinction is the distinction between cardinal and dependent virtues. Accordingly, Chen proposes that in addition to *dao* and *de*, the Confucian scheme consists of *ren*, *li* and *yi* as the basic, cardinal concepts. This thesis is well-supported by the recurrence of such concepts and their fundamental importance throughout the history of Confucianism.

4 The ethical framework of Confucianism

The foregoing pertains to the question of identifying basic, cardinal concepts as contrasted with dependent concepts. A more formidable problem remains as to how these basic concepts are related to one another. The following discussion presents a sketch of a philosophical reconstruction, which is essentially a conceptual experiment. The sketch offers a general characterization of Confucian ethics as a form of virtue ethics, and provides a sample of how such basic notions as *li* and *yi* can be shaped in response to questions deemed important for the development of a Confucian moral philosophy.

The Confucian ethical framework comprises the five basic concepts: *dao*, *de*, *ren*, *yi* and *li*. The best initial approach is to regard these, with a minimum of interpretation, as ‘focal notions’, that is, terms that function like focal lenses for conveying distinct though not unrelated centres of ethical concern. As generic terms, focal notions are amenable to specification in particular contexts, thus acquiring specific or narrower senses. This distinction is an adaptation of Xunzi’s distinction between generic terms (*gongming*) and specific terms (*bieming*). However, a term used as a specific term in one context may in another context be used as a generic term subject to further specification. In other words, the use of a term in either the generic or specific sense is entirely relative to the speaker’s purpose on a particular occasion, rather than to any theory concerning the intrinsic characters of terms or the essential attributes of things.

As noted earlier, *dao* is an evaluative term. Its focal point of interest lies in the Confucian vision of the good human life as a whole or the ideal of human excellence. Commonly rendered as ‘the way’, *dao* is functionally equivalent to the ideal ‘way of life’. Unlike other basic terms, *dao* is most distinctive as an abstract, formal term in the highest generic sense, that is, subject to general specification by way of such virtue (*de*) words as *ren*, *li* and *yi*. As *de* is an individual achievement through personal cultivation, when a person succeeds in realizing *dao*, they

have attained such basic *de* as *ren, li* and *yi*. The specification of *de*, apart from *ren, li* and *yi*, can take a variety of forms or dependent virtues such as filiality, respectfulness or trustworthiness. In this sense, *de* is an abstract noun like *dao*, but it depends on *dao* for its distinctive character. *De* is thus functionally equivalent to ethical virtue. Thus, the opening remark of the *Daxue (Great Learning)* points out that the way of great learning or adult, ethical education lies in the clear exemplification of the virtues (*ming mingde*) (see Daxue; Moral education; Moral development). With its emphasis on *dao* and *de*, Confucian ethics is properly characterized as an ethics of virtue, but more informatively as an ethics of *ren*, *li* and *yi*, relative to their concrete specification or particularization by terms of dependent virtues (for example, filiality, respectfulness, integrity). As generic, focal terms, *ren*, *li* and *yi* are specific terms relative to *dao* as a generic term. Differently put, implicit in Chen's account is a distinction between basic, interdependent virtues (*ren*, *li* and *yi*) and dependent virtues (filiality, respectfulness and so on) (Chen 1976). As indicated earlier, the latter are dependent in the sense that their ethical import depends on direct or indirect reference to one or more of the basic, interdependent virtues of *ren*, *li* and *yi* (see Virtue ethics).

5 *Ren*

While *ren*, commonly translated as 'benevolence', has a long history of conceptual evolution and interpretation, as a focal notion it centres its ethical interest on love and care for one's fellows, that is, an affectionate concern for the well-being of others - the one persistent idea in the Confucian tradition. For this reason, English translators often render *ren* as 'benevolence', suggestive of the use of 'benevolence' in Francis Hutcheson and David Hume. Perhaps a more literal translation of *ren*, however, is 'human-heartedness' or 'humanity', since *ren* is basically an idea of love or concern for the well-being of human community, a specification of the concrete significance of the Confucian *dao* (see Community and communitarianism §1). This core meaning of *ren* as fellow-feeling is found in the *Analects*; it is reported that Confucius once said to his disciple Zengzi, 'My *dao* has one thread that runs through it.' Zengzi construed this *dao* to consist of *zhong* and *shu*, an interpretation widely acknowledged as a method for pursuing *ren* (*Analects* 4.15, in Lau 1979: 74) While the relation between*zhong* and *shu* has divergent interpretations, *zhong* may be rendered as 'doing one's best', and *shu* as 'consideration' (of other people's feelings and desires). In this light, Confucian ethics displays a concern for both self-regarding and other-regarding virtues.

However, the acquisition of these virtues presupposes a locus in which these particular, dependent virtues are exercised. Thus among the dependent virtues, filiality, brotherhood or sisterhood are primary, for the family is the natural home and the foundation for the extension of *ren*-affection. Thus friendship is viewed as a fundamental human relationship along with those of husband-wife and parent-child. In Song and Ming Confucianism (for example, in Cheng Hao and Wang Yangming), *dao* is sometimes used interchangeably with *ren*. In this manner, *ren* attained the status of a supreme, all-embracing ethical ideal of the well-being of every existent thing, human or non-human, animate or inanimate. Confucius' vision of a well-ordered human society is transformed into the vision of the universe as a moral community. In this conception, anything that is an actual or potential object of human attention is considered an object of human concern. Exploitation of human and natural resources must be subject to evaluation in terms of *dao* as an all embracing ethical ideal of existence. This ideal of *dao* makes no specific demands on ordinary humans. For the most part, conflict of values is left to individual determination, though the welfare of the parents is always the first consideration. Thus, the concrete significance of *dao* is open to the exercise of *yi*, the agent's sense of rightness.

6 *Yi* and *li*

The exercise of *yi*, usually rendered as righteousness or rightness, depends on ethical education based on *daotong* or the tradition of the community of interpretation; that is, the reasoned interpretation of the educated members of the community informed by *sensus communis*, a sense of common interest, a regard for *dao* as the ideal unifying perspective. Disagreement or dispute on the pragmatic import of *dao* is expected, as members of the community of interpretation have their own conceptions of human excellence (*shan*) and possibilities of fulfilment. The ethical solution of conflict of interpretation lies in transforming the disagreement into agreement in the light of *sensus communis*, not in a solution defined by agonistic debate which presumes that there are impartial judges who can render their corporate decision in terms of majority vote. Unlike contemporary democratic polity, the majority rule cannot be reasonably accepted as a standard for setting ethical disagreement. The ethical tradition provides the background and guidelines to ethical conduct. Normative ethical theories have value because they provide different ways of assessing the significance of tradition. Like the basic concepts of Confucian ethics, they are focal

notions for important centres of ethical concern, for example, duty and interest (private or public), or in recent terminology, agent-relative and agent-neutral reasons for action (see Moral agents).

The notion of *li* focuses on the ritual code (see Law and ritual in Chinese philosophy). For this reason, it is commonly rendered as ‘rites’, ‘ritual’, ‘propriety’, or ‘ceremonials’. The ritual code is essentially a set of rules of proper conduct pertaining to the manner or style of performance. As *yi* is incompatible with exclusive regard for personal gain, the *li* set forth the rules of ethical responsibility. For Confucius and his followers, the *li* represent an enlightened tradition. As D.C. Lau has put it:

> The rites (*li*) were a body of rules governing action in every aspect of life and they were the repository of past insights into morality. It is, therefore, important that one should, unless there are strong reasons to the contrary, observe them. Though there is no guarantee that observance of the rites necessarily leads, in every case, to behaviour that is right, the chances are it will, in fact, do so.
>
> (Lau 1979: 20)

Yet, the ethical significance of *li* is determined by the presence of the spirit of *ren*. As Confucius once said, ‘If a man has no *ren*, what has he to do with *li*?’ (*Analects* 3.3, in Lau 1979: 67). Since the ritual code represents a customary practice, the early Confucians, particularly Xunzi and the writers of some chapters in the *Liji*, were concerned with providing a reasoned justification for compliance with *li* or traditional rules of proper conduct. As Arthur Waley aptly remarks: ‘it was with the relation of ritual [*li*] as a whole to morality and not with the details of etiquette and precedence that the early Confucianists were chiefly concerned’ (Waley 1938: 67) The same concern with reasoned justification is evident in Song and Ming Confucianists (for example, Zhu Xi and Wang Yangming) who maintain that the significance of *li* (ritual) lies in its rationale (*li zhi li*).

The ethical significance of *yi*, in part, is an attempt to provide a rationale for the acceptance of *li*. *Yi* focuses principally on what is right or fitting. The equation of *yi* with its homophone meaning ‘appropriateness’ is explicit in the *Zhongyong*, 20 (see Zhongyong), and is generally accepted by Confucianists (for example, Xunzi, Li Gou and Zhu Xi). However, what is right or fitting depends on reasoned judgement. As Xunzi observes: ‘The person concerned with *yi* follows reason’ (*Xunzi* XV, in Li 1979: 328) Thus, *yi* may be construed as reasoned judgement concerning the right thing to do in particular exigencies. Li Gou, a Song Confucian, justly reminds his readers that *yi* is ‘decisive judgement’ that is appropriate to the situation at hand.

In light of the foregoing, the interdependence of basic notions may be stated as follows. Given *dao* as the ideal of the good human life as a whole, *ren*, *li* and *yi*, the basic Confucian virtues (*de*), are constitutive rather than mere instrumental means to its actualization. In other words, the actualization of *dao* requires the co-satisfaction of the standards expressed in *ren*, *li* and *yi*. Since these focal notions pertain to different foci of ethical interest, we may also say that the actualization of *dao* requires a coordination of three equally important centres of ethical interest and endeavour. The connection between these foci is one of interdependence rather than subordination. Thus in the ideal case, *ren*, *li* and *yi* are mutually supportive and adherent to the same ideal of *dao*. When *dao* is in fact realized, *ren*, *li* and yi would be deemed constituents of this condition of achievement. When, on the other hand, one attends to the prospect of *dao*-realization, *ren*, *li* and *yi* would be regarded as complementary foci and means to *dao* as an end. In sum, *ren*, *li* and *yi* are complementary foci of human interest.

7 The scope and functions of *li*

Because of its distinctive character and role in Confucian ethics and its pervasive influence in traditional China and contemporary critique, the notion of *li* requires special attention (see Law and ritual in Chinese philosophy). Implicit in the notion of *li* is an idea of rule-governed conduct. In the *Liji (Book of Rites)*, the subject matter ranges from ritual rules (or formal prescriptions) concerning mourning, sacrifices, marriage and communal festivities to the more ordinary occasions relating to conduct towards ruler, superior, parent, elder, teacher and guest. Because of its emphasis on the form or manner of behaviour, *li* is often translated as ‘religious rites’, ‘ceremony’, ‘deportment’, ‘decorum’, ‘propriety’, ‘formality’, ‘politeness’, ‘courtesy’, ‘etiquette’, ‘good form’ or ‘good behaviour’. These renderings are misleading without understanding the different functions of *li*. At the outset, it is important to note that for Confucians the *li* are an embodiment of a living cultural tradition; that is, they are subject to modification in response to changing circumstances of society. Thus some writers of the *Liji* point out that the *li* are the prescriptions of reason, and that any ritual rule that is deemed right and reasonable (*yi*) can be considered a

part of *li*. On one plausible interpretation, the traditional ritual code represents no more than a codification of ethical experiences based on the concern with *ren* and *yi*. In this light, the *li* are in principle subject to revision or replacement. In the spirit of Zhu Xi, we may say that a Confucian must reject ritual rules that are burdensome and superfluous and accept those that are practicable and essential to the maintenance of a harmonious social order. However, any reasoned attempt to revise or replace *li* presupposes an understanding of their functions. It is this understanding that distinguishes the Confucian scholar from a pedant, who may have a mastery of rules without understanding their underlying rationales. For elucidation, we rely mainly on a reconstruction of Xunzi's view, since we find in some of his essays the most articulate concern for and defence of *li* as an embodiment of a living, cultural tradition (see Xunzi).

With regard to any system of rules governing human conduct, one can always raise questions concerning its purpose. In Confucian ethics, the *li*, as a set of formal prescriptions for proper behaviour, have a threefold function: delimiting, supportive and ennobling. The *delimiting* function is primary, in that the *li* are fundamentally directed to the prevention of human conflict. They comprise a set of constraints that delineate the boundaries of pursuit of individual needs, desires and interests. The *li* purport to set forth rules of proceeding in an orderly fashion, ultimately to promote the unity and harmony of human association in a state ruled by a sage king imbued with the spirit of *ren* and *yi*. This orderliness consists of social distinctions or divisions in various kinds of human relationships (*lun*), namely, the distinctions between ruler and minister, father and son, the eminent and the humble, the elder and the younger, the rich and the poor, and the important and unimportant members of society. In abstraction from the connection with *ren* and *yi*, the delimiting function of *li* may be compared to that of negative moral rules or criminal laws. Like rules against killing, stealing or lying, the *li* impose constraints on conduct. They create paths of obstruction, thus blocking certain moves of agents in the pursuit of their desires or interests. The *li*, in effect, stipulate the conditions of eligibility or permissibility of actions. They do not prejudge the substantive character or value of individual pursuit. They provide information on the limiting conditions of action, but no positive guidance as to how one's desires may be properly satisfied. Put differently, the *li* tell agents what goals *not* to pursue, but they do not tell them how to go about pursuing goals within the prescribed limits of action.

Apart from the delimiting function, the *li* have also a *supportive* function; that is, they provide conditions or opportunities for satisfaction of desires within the prescribed limits of action. Instead of suppressing desires, the *li* provide acceptable channels or outlets for their fulfilment. In an important sense, the supportive function of *li* acknowledges the integrity of our natural desires. So long as they are satisfied within the bounds of propriety, we accept them for what they are whether reasonable or unreasonable, wise or foolish, good or bad. The main supportive function of *li* is the redirection of the course of individual self-seeking activities, not the suppression of motivating desires. Just as the delimiting function of *li* may be compared with that of criminal law, their supportive function may be compared with that of procedural law, which contains rules that enable us to carry out our wishes and desires (for example, the law of wills and contracts). The *li*, like these procedural rules, aid the realization of desires without pronouncing value judgments.

The focus on the *ennobling* function of *li* is a distinctive feature of Confucian ethics and traditional Chinese culture (see Self-cultivation, Chinese theories of). The keynote of the ennobling function is 'cultural refinement', the education and nourishment (*yang*) of emotions or their transformation in accord with the spirit of *ren* and *yi*. The characteristic concern with the form of proper behaviour is still present. However, the form stressed is not just a matter of fitting into an established social structure or set of distinctions, nor is it a matter of methodical procedure that facilitates the satisfaction of the agent's desires and wishes; rather, it involves the elegant form (*wen*) for the expression of ethical character. In other words, the ennobling function of *li* is directed primarily to the development of commendable or beautiful virtues (*meide*). The 'beauty' (*mei*) of the expression of an ethical character lies in the balance between emotions and form. What is deemed admirable in the virtuous conduct of an ethically superior person (j*unzi*) is the harmonious fusion of elegant form and feelings. In the ideal case, a *li*-performance may be said to have an aesthetic dimension. In two different and related ways, a *li*-performance may be said to be an object of delight. In the first place, the elegant form is something that delights our senses. It can be contemplated with delight quite apart from the expressed emotional quality. In the second place, when we attend to the emotion or emotional quality expressed by the action, which we perceive as a sign of an ethical virtue or character, our mind is delighted and exalted, presuming of course that we are also agents interested in the

promotion of ethical virtues in general. Respect for traditional rites of mourning and sacrifices is an expression for the concern with *ren* and *li*, because such practices exemplify the Confucian ideal of humanity; it is a sort of religious concern without endorsing any religious beliefs and practices.

8 The Confucian tradition

If the set of *li*, or rules of proper conduct, is viewed as a repository of traditional insights, a question then arises concerning the Confucians' conception of their own tradition. Like other enduring ethical or religious traditions which extend across history (such as Buddhism or Christianity), the Confucian or Ru tradition, as embodied in the notion of *daotong*, has often been the target of the contemporary critique. According to one familiar appraisal, the Ru tradition is out of tune with our times. Like any cherished cultural artefact, it is best revered as a relic of the past. Moreover, many adherents of the Confucian tradition are dogmatic; they are unwilling to accept reasonable proposal for change or modification of some components of the tradition.

Replying to this charge, a Confucian thinker or scholar might point out that, to a certain extent, the critique is reasonable. Throughout its long history, there is a recurrent tendency of many adherents of the Confucian tradition to institute orthodoxy and uphold their perceived values of the tradition as the true values of the tradition, indifferent to the distinction between perceived and real values. A personal ascription of value to an object cannot be logically equated with the value inherent in the object. Understanding a living tradition requires an appreciation of the distinction between the actual past and the perceived past, and the distinction between a living, robust tradition and a dying, decaying tradition. In the words of Jaroslav Pelikan, 'Tradition is the living faith of the dead, traditionalism is the dead faith of the living' (Pelikan 1984: 65).

Confucianism, in the words of Thomé Fang, is 'a constructive philosophy of comprehensive harmony invested with creative energies of life' (Fang 1981: 33). Although this is a summary statement of the outcome of Fang's metaphysical inquiry, it is an apt characterization of the vitality of the Confucian *dao* or way as an ethical vision of the good human life, an ideal amenable to varying interpretations of its concrete significance in different times and places. *Dao* is an ideal theme rather than an ideal norm or supreme principle of conduct (Cua 1978, ch. 8). It is fundamentally a unifying perspective for harmonizing the diverse elements of moral experience. To adopt the *dao* is to see human life, in its morally excellent form, as possessing a coherence in which apparently conflicting elements are viewed as eligible components of an achievable harmonious order (Cua 1982, ch. 3). It is this vision of *dao* that renders intelligible the idea of a Confucian ethical tradition as a living tradition enriched by its historic past, interpreted by adherents as having a present and prospective significance (see Dao).

9 Xunzi and Zhu Xi

Xunzi and Zhu Xi are perhaps the most articulate proponents of the importance of learning the classics as an indispensable means to inculcating a respect for the historical aspect of tradition. Xunzi points out that learning is an unceasing process of accumulation of goodness, knowledge, and practical understanding: 'If an ethically superior person (*junzi*) studies widely and daily engages in self-examination, his intellect will become enlightened and his conduct be without fault.' In general, the programme of learning 'commences with the recitation of the classics and ends with the study of *li* (rituals)'. Its purpose, however, is 'first to learn to become a scholar and ultimately to become a sage'. The classics are presumed to embody the concrete significance of *dao*. For example, 'the *Odes* give expression to the will (*zhi*) or determination [to realize *dao*]; the *History* or *Book of Documents* to its significance in human affairs; the *Li* or *Rites* to its significance in conduct; the *Music* to its significance in promoting harmony; and the *Spring and Autumn Annals* to its subtleties.' Notably, these classics are not self-explanatory, thus guidance from perceptive teachers is required. For example, 'the *Li* and *Music* present us with models, but no explanations; the *Odes* and the *History* deal with ancient matters and are not always pertinent; the *Spring and Autumn Annals* are terse and cannot be quickly understood' (*Xunzi* I, in Li 1979: 2-14; trans. in Watson 1963: 15-20).

Indeed, for Confucius as for Mencius and Xunzi, the *li* represent an ethical and cultural tradition (see Confucius). Learning to be a moral agent consists in part in appreciating 'the accumulated wisdom of the past'. Compliance with *li* as a set of formal prescriptions of proper behaviour without regard to *ren* and particular circumstances would be deemed unreasonable. It is perhaps for this reason that Confucius stresses *yi* (a sense of rightness) rather than preconceived opinions in coping with novel and exigent situations. Mencius is emphatic that the relevance of

a *li*-requirement must be considered in the light of weighing (*quan*) particular circumstances. In a similar spirit, Xunzi emphasizes the exercise of *yi* in responding to changing circumstances of human life. In general, the enforcement of laws and other rules of conduct depends on superior or exemplary persons (*junzi*) who have not only a knowledge of the subject matter but also an understanding of their underlying purposes, in addition to having a sense of priority and an ability to respond appropriately to changing affairs. Learning to become a sage (*shengren*) must begin with the study of the classics with a view to discerning their actuating significance in living contexts (see Chinese Classics).

The Confucian respect for the authority of the past in relation to the present requires not only a critical understanding of the practical significance of the classics but, more importantly, a critical assessment of the ethical character and achievement of contemporary adherents of the tradition. Thus Xunzi urges his readers to distinguish common people from three sorts of Confucians (Ru): the vulgar or conventional (*suru*), the refined or cultured (*yaru*) and the great or sagely Confucians (*daru*). This distinction between three types of Confucians may be seen to be motivated by Xunzi's desire to respond to the internal challenges within the Confucian tradition - a reminder and a warning to his fellow Confucians against uncritical intellectual and practical affiliation (*Xunzi* VIII, in Li 1979). His critique of Mencius on the relation between morality and human nature is a well-known illustration of an internal conflict between different interpretations of a key aspect of Confucian ethical tradition. Like Mencius, Xunzi is also quite aware of the need to engage in argumentation to answer external challenges to the Confucian tradition (*Xunzi* XXIII, in Li 1979). For Mencius, there was no alternative but to engage in disputation since the *dao* of the sages, embodied in Yao and Shun, had in his own time been obscured by the prevailing teachings of Yang Zhu and Mozi.

In a similar spirit, Xunzi attacks the views of a number of philosophers, for example, Mozi, Hui Shi, Songzi and Shen Dao, as well as Laozi and Zhuangzi. Xunzi considers most of their doctrines pernicious because, though often presented in elegant language and composition, they also present erroneous conceptions of the distinction between right and wrong and between order and disorder. However, it is noteworthy that Xunzi's critique explicitly acknowledges that 'some of what they advocate has a reasoned basis, and thus their statements appear plausible' (*Xunzi* VI, in Li 1979: 94). In the light of his holistic conception of *dao*, many philosophical views are unacceptable not because they are totally erroneous, but because they grasp only partial aspects of *dao* and exaggerate these at the expense of other aspects. In sum, in Xunzi we find a Confucian philosopher who exemplifies a concern with defending the Confucian tradition against both internal and external challenges, and who is at the same time quite capable of critical adoption of non-Confucian views which he deems reasonably acceptable.

Zhu Xi's conception of the Confucian tradition, *daotong*, commonly rendered as 'transmission of *dao*', is a conception central to the orthodox tradition of neo-Confucianism (see Neo-Confucian philosophy). Because of its religious connotation, the notion of orthodoxy quite naturally suggests an uncritical adherence to conventional or currently accepted beliefs as possessing an unquestioned authoritative status. As de Bary has instructively shown, however, *daotong* is better construed as 'repossession of *dao*' or 'reconstitution of *dao*', recalling Pelikan's distinction between a living tradition and traditionalism (de Bary 1981: 2).

As Tu Wei-ming remarks, Zhu Xi's study of the classics represents 'serious efforts to revitalize the tradition [which] involved creative adaptation as well as faithful interpretations' (Tu 1979: 134). For example, in his detailed recommendations of classics for examinations, apart from some commentaries, Zhu Xi stresses the self-critical study of original texts: 'In studying the classics one must have regard for the considered views of former scholars and extrapolate from them, aware that they are not necessarily conclusive but must be weighed as to what they understood and what they missed; then finally all this must be reflected upon in one's own mind to verify it' (*Zhuzi yulei* 3:37, in Li 1962, 1638-42). Zhu Xi also recommends non-orthodox philosophers of early China such as Xunzi, Han Feizi, Laozi (see Daodejing) and Zhuangzi. De Bary rightly reminds us that Zhu Xi's notion of *daotong* should not be construed in a manner that suggests a passive reception and transmission of the Confucian Way, for it involves an activity of revitalization and rediscovery as well as recovery of the meaning of the tradition or, in contemporary language, an activity of constructive or reconstructive interpretation of the tradition: 'In fact, Chu Hsi [Zhu Xi] emphasized the discontinuities in the tradition almost more than the continuities, and underscored the contributions of inspired individuals who rediscovered or "clarified" the Way in new forms' (de Bary 1981: 99).

Both Xunzi and Zhu Xi emphasize the role of inspired and insightful persons regarding classical learning. This emphasis somewhat echoes Confucius' notion of *junzi* or paradigmatic individuals, that is, persons, who through their life and conduct embody *ren*, *li*, *yi* and other ethical excellences (see §2). The *junzi* are the exemplars of the actuating significance of the Confucian tradition, serving as standards of inspiration for committed agents. These paradigmatic individuals are generally ascribed an authority by their contemporary adherents. The authority, however, is based on the acknowledgement of their superior knowledge and achievement, and especially their exercise of yi in interpretive judgements concerning the relevance of rules in exigent situations, or in Xunzi's words, on *dao* and *de* (virtue). However, while possessed of an authoritative ethical status, as standard bearers and interpreters of culture the *junzi* are not arbiters of moral disputes, for their interpretations of the Confucian tradition represent individual efforts toward the repossession or reconstitution of *dao*, thus essentially contestable and subject to reasoned assessment of their contemporaries and posterity.

Implicit in the foregoing characterization of the Confucian tradition as a living tradition is the notion of tradition as an interpretive concept. For the most part, major Confucian philosophers stress the importance of classical education and the role of teachers as *junzi* or paradigmatic individuals, because they are thought to exemplify the best spirit of Confucius. Notably, Confucius' conception of *junzi* focuses on some salient characteristics. In addition to their pursuit of *dao*, the concern with *ren*, *li* and *yi*, they are also persons of integrity, catholicity and neutrality. The integrity is exemplified in their unwavering concern with the harmony of words and deeds (Cua 1978, ch. 5). This stress on the role of *junzi* as a guiding standard of education and moral conduct naturally gives rise to the question on the possibility of modification and transformation of the Confucian tradition. Indeed, if tradition is an interpretive concept, some account must be given on how changes may be viewed as consistent with the conservation of tradition.

10 Transformation of the Confucian tradition

In the Confucian context, this problem of transformation of the tradition is best considered in terms of the distinction and connection between *jing* (the standard) and *quan* (the weighing of circumstances). The former pertains to the operative, established standards of conduct, the latter to the specific circumstances. *Quan* may be regarded as *jing* prior to the determination of its significance in actual, particular situations. In other words, *jing*, the established standards of conduct, depend on *quan* in the sense that their application is undetermined prior to actual circumstances. When such a determination is made, *quan* would become part of *jing*, given the assumption that the judgments are accepted by the Confucian community of interpretation. Concisely put, *jing* is the determinate *quan*, and *quan* is the indeterminate *jing*. Of course, both represent the constant (*chang*) and the changing (*bian*) aspects of *dao*.

More importantly, the exercise of *quan* entails a concern with *yi* or rightness of judgement. Right judgement is necessary not only in dealing with the hard cases of the moral life, but also with normal situations (*jing*) where the intelligent adherent of the tradition confronts the problem of interpretation and application. In both sorts of situation the agent has the same moral objective, that is, to do the right thing. This is perhaps the point of Zhu Xi's saying that *quan* is unavoidably exercised in changing situations that fall outside the scope of the regular practice of *daoli* (moral norm):

> When *quan* attains equilibrium (*zhong*), it does not differ from *jing*', that is, they have achieved the same moral objective. In both cases they are governed by the exercise of *yi* or one's sense of rightness. For Zhu Xi, *yi* constitutes the *guan*, the thread that runs though *jing* and *quan*.
>
> (*Zhuzi yulei* 3:37, in Li 1962, 1638-42)

The foregoing reflections on the distinction and connection between *jing* and *quan* afford us an answer to the question of the possibility of change or modification of the Confucian tradition of *dao*. Intelligent adherents of the Confucian tradition can deploy the sceptical challenge without fear of the corruption of the tradition (see Moral scepticism). The dynamic interplay of *jing* and *quan* in relation to constancy (*chang*) and change (*bian*) shows that the distinction is not a fixed or absolute distinction. As Dai Zhen points out, what is deemed important or unimportant in our assessment will vary in different times and places (Dai 1777 [1975]: 125). Put differently, the substantive content of the tradition of *dao* cannot be considered settled without prejudging the merits of particular circumstances. The exercise of *quan* in any situation requires a careful examination and analysis of all the relevant

factors involved.

Quite naturally, one may raise the question of justification for such judgements in exigent circumstances. In normal situations, the *li* are quite sufficient for action guidance insofar as they are informed by a concern for *ren*. The problem of reasoned justification for such judgments has not received attention from most Confucian thinkers, except Xunzi. However, even in the works of Xunzi we do not find any articulate answer to this problem, though his works do provide materials for constructing a response. In the first place, Xunzi is explicit that any discussion is valuable because there exist certain standards for assessment, and these standards pertain principally to conceptual clarity, respect for linguistic practices and evidence, and the requirement of consistency and coherence in discourse. A philosophical reconstruction along the lines of the theory of argumentation presents an interesting Confucian view of justification in terms of rational and empirical standards of competence, along with certain desirable qualities of participants in ethical discourse. In this reconstruction of Xunzi's works, ethical justification is a phase of discourse, preceded by explanatory efforts in the clarification of normative claims responsive to a problem of common concern among participants. This in turn presupposes that queries concerning the proper uses of terms are understood by participants in ethical argumentation (Cua 1985a).

11 Historical appeal

As widely noted by contemporary writers on Confucian ethics, in argumentative discourse the Confucians are fond of appeal to historical events and paradigmatic individuals. This ethical use of historical knowledge and beliefs is a pervasive feature of Confucianism. A serious student of Chinese philosophy cannot accept the common view that Chinese thinkers are inclined to be uncritical towards their history, or that they believe that history provides the exclusive guidance for present problems and perplexities. A careful examination of the works of Xunzi refutes this thesis. The Confucian respect for tradition and its history, and for exemplary historical persons and events, is best appreciated in terms of four ethical, argumentative uses of the past or historical appeal. These are the pedagogical, rhetorical, elucidative and evaluative uses (see History, Chinese theories of).

For Xunzi, the primary aim of moral education is the transformation of man's native but problematic motivational structure (for example, feelings and desires) by way of knowledge of standards of *ren*, *yi* and *li*. One learns for the sake of doing; knowing the right and the good is for the sake of acting in accord with such knowledge. Learning, however, is not equivalent to the mere acquisition of knowledge but more essentially requires understanding and insight. For Xunzi, the basic philosophical issue in moral education pertains to the rational coordination of the intellectual and volitional activities of the mind (*xin*) by means of the *dao*. Given the autonomy of mind, one can choose to accept or reject its guidance. If the mind is directed by reason and nourished with clarity and is not perturbed by extraneous matters, 'it will be capable of determining right and wrong and of resolving doubts' (*Xunzi* XXI, in Li 1979: 490; trans. in Watson 1963: 131). In sum, the pedagogical use of the historical appeal points not only to models who are worthy or unworthy of emulation, but more significantly to models functioning as reminders in moral learning and conduct that appeal especially to what is deemed in the real interests of the learner. Notably, gentle suasion rather than coercion is involved, as the individual still retains the freedom to accept or reject it. This constitutes the argumentative value of the pedagogical function of the historical appeal rather than the mere exhibition of moral exemplars. The latter's effectiveness lies primarily in the appeal to paradigmatic individuals (*junzi*) (see Moral education; Moral development).

The rhetorical function of the historical appeal is essentially a problem of assurance, of appeal to plausible presumptions or shared beliefs and trustworthiness (*xin*) (see Xin). When I present reasons supporting my interpretation of the Confucian tradition, I will deploy those unquestioned assumptions in discourse. Also, I expect my fellow Confucians to believe me when I cite information that is presumably known to members of my community. Obviously, the historical appeal functions as a technique for assuring the audience that the thesis maintained is consonant with shared historical beliefs, and obviates having to state reasons for their support. It also constitutes a technique of discounting alternative views, shifting the burden of proof to a possible adversary. These uses, of course, are subject to further challenge, for the rational acceptability of the thesis and an assurance that the thesis is not a mere imaginative contrivance to avoid questioning.

The elucidative function of the use of history attempts to clarify the relevance of the past for the present. This is basically an expression of the respect for tradition, clarifying, in interpretation, one's intelligent, critical understanding of the tradition. Of course, the question of evaluation arises in serious Confucian discourse. Inherent

in the use of historical characters for elucidating and demonstrating the applicability of an ethical thesis is the implicit claim that human history is the proper subject of ethical appraisal. However, this claim is explicit in the evaluative use of the historical appeal.

Notably, the elucidative use of the historical appeal is retrospective; that is, it is the use of the appeal to the past for judging the present (*yigu chijin*); while the evaluative use is prospective, that is, for the sake of determining the relevance of the past to the present (*yijin chigu*). In the retrospective use, Xunzi is clearly recommending the adoption of a standpoint based on historical knowledge or beliefs for the purpose of maintaining or assessing the adequacy of current beliefs. The prospective use, however, stresses our knowledge and understanding of our present problematic situations as a basis for assessing the unexamined claims based on the past as a guidance to the present. Both the retrospective and prospective uses of the historical appeal are essentially critical, and can be used either in the positive defence of one's thesis or in the negative evaluation of another's thesis or both. In J.O. Urmson's words, we have here a distinction between *standard-invoking* and *standard-setting* aspects of normative discourse (Urmson 1968: 68). In effect, the retrospective use of the historical appeal invokes an established framework with its operative criteria or standards for justification of ethical judgments. Of course, one can always raise external questions about an established practice.

The prospective use of the historical appeal reverses the standpoint of the retrospective one. Human history is seen as a subject matter rather than as a basis for ethical judgment. In adopting this standpoint, one can no longer avail oneself of the presumption of the truth of historical beliefs without critical examination, nor can one presume the existence of shared historical knowledge. The key issue here lies in the present evidential grounding of ethical claims (for further discussion see Cua 1985b).

In closing, it may be noted that Confucian ethics, like any normative system, presents conceptual problems of interpretation and reconstruction. Attention here has been focused on the Confucian scheme of basic notions and the idea of Confucian tradition (*daotong*). Doing full justice to the range of Confucian concerns also involves a critical consideration of divergent views on such topics as the relation of the basic notions to human nature, the role of emotions in ethical deliberation and justification, the place of law in an ideal social, political union, and the metaphysical grounding of *dao*, particularly in the connection of the human and the natural orders. A serious student of Confucian philosophy must consider these problems with reference both to the divisive efforts and tension within the history of Chinese philosophy, and to the significance of these efforts to of Western philosophical inquiries.

Confucian philosophy, Japanese

Confucian philosophy is said to have arrived in Japan as early as the third century AD, but it did not become a subject of meaningful scholarly inquiry until the seventh century. The 'Confucianism' to which Japanese elites and scholars were first attracted represented fields of knowledge concerned more with ontology and divination than with social ethics and politics. Because of the priority given to birth over talent in official appointments, Confucianism in Japan remained more a gentlemanly accomplishment and never approached the status it had in China, where mastery of its teachings represented a gateway to officialdom. Intellectually, Confucian philosophy was overshadowed both in Japan and on the continent at this time by the teachings of Buddhism, which provided answers both to spiritual and metaphysical concerns.

Confucianism in China was refashioned in the eleventh and twelfth centuries by a number of scholars, of whom Zhu Xi was the most prominent. He revised the curriculum, restored social and ethical concerns to positions of centrality within the tradition and formulated a new rationalistic ontology. His teachings won a broad following among intellectuals in China and eventually earned the government's endorsement as the official interpretation for China's examination system.

From the seventeenth century onwards, Zhu Xi's teachings reached a comparably distinguished position within scholarly circles in Japan, though the government's endorsement of the Hayashi family as official interpreters of Zhu Xi's teachings was the limit of the official authorization of that philosophy in Japan. Though the idealistic Wang Yangming school challenged Zhu Xi's teachings in Japan as it had in China, the more effective challenge was mounted by the classicist teachings known as Ancient Studies. These scholars, of whom the best known was Ogyū Sorai, sought the 'true message of the sages' by emphasizing direct study of the ancient core texts of Confucianism rather than the exegesis on those classics by Zhu Xi and others.

Confucian philosophy contributed to the rationalism, humanism, ethnocentrism and 'historical mindedness' of Tokugawa Japan. The teachings were also responsible for changing fundamental ontological and epistemological assumptions, while also opening intellectual circles to unprecedented pluralism and diversity. Towards the end of the Tokugawa period in the mid-nineteenth century, Confucian philosophy (particularly in the variety fashioned by Wang Yangming) also provided inspiration and justification for those activist reformers who succeeded in overthrowing the old order.

During the modern period, Confucian philosophy has been identified with the Tokugawa tradition which has been at times idealized and and at other times vilified. Nonetheless, a number of the assumptions central to Confucian philosophy continue to characterize much popular and intellectual thought in contemporary Japan, as well as those ethics that tend to be most admired, even though actual knowledge of Confucian philosophy does not appear to be widespread any longer in Japan.

1 Confucian philosophy in early Japan

The earliest extant Japanese histories record that in AD 285 - the actual date was probably a century or so later - Wani, of the Korean kingdom of Paekche, brought copies of the *Analects* (*Lunyu*; in Japanese, *Rongo*) of Confucius and the *Qianziwen* (Thousand Character Classic; *Senjimon* in Japanese) from Korea to Japan (see Confucian philosophy, Korean). Even though most scholarship on Japan tends to identify this introduction of Confucian texts with the introduction of Confucian philosophy, it is nonetheless clear that immigrants from China and Korea who were familiar with the Confucian classics surely preceded the gift of these texts and probably themselves represent the actual introduction of Confucianism to Japan.

Confucianism does not appear to have provoked the same measure of suspicion or antagonism as other forms of continental East Asian civilization being introduced to Japan at this time, and the fact that Japanese interest in Confucianism continued to grow is suggested by the arrival in the sixth century of authorities from Paekche on the Confucian classics. Thereafter, with the coincident introduction of Buddhism (also from Korea), Confucian philosophy came to be regarded in Japan as one component of the richly variegated culture and civilization of continental East Asia, both of which were increasingly welcomed and responsible for major changes in Japan.

The 'Confucianism' to which Japanese elites were first exposed, however, was not the ethical socio-political

teaching represented by texts like the *Analects* or the *Mengzi* (see Confucius; Mencius) which were not at that time regarded as the core of the tradition. Instead, this early continental Confucianism represented the elaboration of metaphysical and cosmological constructions dating from Han dynasty China (206 BC- AD 220) (see Chinese philosophy). According to these teachings, an emperor was the supreme Son of Heaven whose correct performance of his role as an intermediary between Heaven above and Earth below was essential to the harmonious processes of the cosmos (see Tian). According to this doctrine human responsibilities lay principally in the area of governmental administration, which if properly executed would then ensure that everything from seasonal change to plentiful harvest would contribute to terrestrial well-being, and of course the greatest responsibility thus rested with those in the highest positions. Accordingly, those in Japan who aspired to a more powerful Chinese-style imperial institution often invoked these claims to further their own interests. Further, by positing the interrelatedness of all phenomena in the human realm with those of the celestial and terrestrial realms, this early form of Confucianism also taught that an understanding of the whole might be inferred from an understanding of individual particulars, and so it came to include such divinatory exercises as geomancy, astrology and numerology. These too enjoyed considerable appeal in Japan.

However, because long-standing aristocratic principles in Japan gave priority to pedigree over either virtue or administrative performance, Japanese Confucianism differed from that on the continent by marginalizing both discussion of imperial virtue as it was believed to promote effective government, and assessment of administrative performance as it was likewise believed to entitle one to career advancement. Thus, it was characteristic in Japan before the seventeenth century to consult 'Confucian' philosophy on such matters as determining auspicious dates or sites for important events or constructions, but only rarely does one find meaningful engagement of Confucian wisdom on how best to order the affairs of human beings or the state.

One example of this peripheral role for Confucian philosophy may be discerned in Japan's first important statement of goals for the polity in terms of the new political thought from the continent, the so-called 'Seventeen Article Constitution' of 604. In this document, its author Prince Shōtoku exhorts Japanese leaders to accept the continental imperial principle using references to Confucianism as only one possible source of justification, with other often more persuasive arguments drawn from such alternative forms of thought as Buddhism and Legalism (see Shōtoku Constitution). Buddhism in Japan, as in China, succeeded in preempting Confucian claims to authority in the realm of governance by itself asserting its role in 'protecting' the government from both natural and supernatural threats (see Buddhist philosophy, Chinese).

This, however, did not prevent Confucianism from making contributions in other areas. For example, one may discern the influence of Confucian philosophy in the seventh- and eighth-century impulse to record Japanese history for posterity, and it is clear that the early refashioning of the previously oral historical tradition sought to depict at least some emperors in the classic guise of benevolent Confucian-style monarchs. These earliest histories in Japan, however, did not reflect certain other perhaps more fundamental Confucian historiographical principles, such as the notion of dynastic change, the Mandate of Heaven as conferred upon those whose virtue entitles them to rule, and historical evidence of Heaven's rewarding the rectification of names whereby responsibilities were expected to conform to title and position.

Further, from time to time as during the reigns of Emperors Daigo (897-930) and Murakami (946-67), Confucianism did receive attention at the imperial court, but such occasions were the exception rather than the rule. Despite the fact that Confucian texts remained part of the curriculum of those aristocrats who trained for positions in service to the imperial court - positions to which their aristocratic birth gave them first claim - Confucian philosophy *per se* was quickly subordinated to Buddhism and came to be regarded for the most part as a teaching of only secular value whose larger truths might all be found in more developed fashion within Buddhism. Indeed, when the Buddhist pioneer Kūkai sought to represent all religious consciousness in terms of ten stages, he ranked Confucianism near the very bottom and second only to the debased consciousness of animal passions, a perspective that was shared widely during succeeding centuries in Japan.

2 Zhu Xi and the Confucian revival

During the eleventh and twelfth centuries in China, where Confucian philosophy had similarly been subordinated to Buddhism, Confucian teachings were revitalized. The curriculum was refashioned to restore the ethical writings of figures like Confucius and his interpreters to a central position, and metaphysical and cosmological teachings

were restructured in a manner that undermined Buddhism's heretofore hegemonic claims to authority in those areas. The central figure in this development was Zhu Xi (1130-1200) who, without diminishing his achievement, is often described as having synthesized the teachings of a number of earlier figures including Zhou Dunyi, Zhang Zai, Shao Yong and the brothers Cheng Hao and Cheng Yi.

Zhu Xi understood the world to be constructed of a combination of principle (*li*; in Japanese, *ri*) and material force (*qi*; in Japanese, *ki*). Principle, a singular term which included both natural and moral principles, has ontological priority over material force and is complete, unchanging, eternal and good. Material force, by contrast, represents the physical stuff of the universe, is changeable, and contains both good and bad elements (see Qi). Together, principle and material force were thus seen by Zhu Xi as comprising the entire physical universe and as operating according to the same rhythms of change and stasis that govern the cosmos.

Within human beings, according to Zhu Xi, principle corresponds to one's original nature (*benran zhi xing*; in Japanese, *honzen no sei*), or in other words, that disposition which humans share at the moment of birth and which is likewise naturally and equally good among all people (see Xing). Similarly, in humans material force is represented by one's specific nature (*qizhi zhi xing*; in Japanese, *kishitsu no sei*), that disposition which is specific to oneself and which varies in its turbidity from one person to the next. Under ideal circumstances when one's emotions are not aroused to excess, one can respond naturally to one's original nature and one's behaviour accordingly will seemingly spontaneously conform to correct norms. At other times, however, one's emotions and desires are agitated to the extent that they interfere with the ability to respond to others with goodness or in a humane manner. Thus the key to goodness, Zhu Xi taught, was learning how to still one's specific nature so that one's original nature might be manifested in all its excellence. This exercise in turn can be facilitated by either of two ways: first, one can study the external world in order to discern the role of principle within it, recognizing that by apprehending truths concerning principle in the world, one has likewise learned something about one's original nature; alternatively, one may cultivate the quality of seriousness (*qing*; in Japanese, *kei*) through such practices as quiet sitting or study of the canonical literature, thereby learning how to still one's potentially disruptive emotional excesses. This twofold praxis gave Zhu Xi's philosophy both intellectually and spiritually compelling properties.

These teachings, often styled 'neo-Confucianism' in European and North American scholarship, reached Japan in the thirteenth century, but aside from a brief period of vogue at the imperial court of Emperors Hanazono (1308-18) and Godaigo (1318- 39), they were taught almost exclusively in Zen monasteries and hence were not regarded as a subject for serious study independent from Buddhism. Such practises as Confucian quiet sitting were thus represented in the monasteries as simply less well-developed versions of such Zen teachings as 'sitting in meditation' (*zazen*). Thus, even though Confucian texts were also included in the curriculum of the Ashikaga *gakkō* (academy) at which scions of this distinguished family trained for service in the *bakufu* (central government), the teachings had the status more of one of the polite gentlemanly accomplishments than that of political philosophy with its own intellectual integrity. The contrast with the continent could not in this respect have been much greater, for there Zhu Xi's teachings were at the root of a radical change in both ontology and epistemology from a fundamentally Buddhist orientation to one which was grounded in Confucianism (see Neo-Confucian philosophy).

3 Tokugawa Confucianism

The relatively low regard in which Confucian philosophy was held in Japan prior to the seventeenth century changed during the Tokugawa period (1600-1868). Spurred on the one hand by the arrival of new Confucian texts from Korea as part of the booty from Japan's unsuccessful invasion of that country, and on the other hand by the Tokugawa government's eventual understanding of the utility of secular ideology in bolstering its claims to legitimate rule, Confucian teachings for the first time in Japan enjoyed the status of an independent subject of scholarly inquiry. Recent scholarship has demonstrated, however, that Confucianism's displacement of Buddhism's hegemony in these areas was a somewhat slower process than had previously been understood, and required the better part of a century to accomplish.

A pioneering figure in this development was Fujiwara Seika (1561-1617), a former Zen priest who became fascinated with the rich diversity of continental Confucian philosophy reflected in the newly imported texts. Seika was attracted to and taught doctrines from a broad range of Chinese and Korean Confucian scholars, including those who challenged the authority of Zhu Xi's teachings. It was Seika's disciple Hayashi Razan (1583-1657)

who, by contrast, became an early champion of the version represented by the teachings of Zhu Xi. Since these teachings had been sanctioned in China since the early fourteenth century as the correct interpretation for the official state-sponsored exams, they were essential to the curriculum of all who aspired to government service in China, and if anything they enjoyed even greater favour among aristocratic and official elites in Korea (see Confucian philosophy, Korean). Hayashi Razan initiated efforts, later continued by his son Hayashi Gahō (1618-80), to win official endorsement of these teachings by Japan's central military government with the Hayashi themselves as the authorized interpreters of this tradition. These efforts bore fruit later when, in 1691, the Shogun Tokugawa Tsunayoshi donated land for the relocation of the Hayashi family's school in Edo (modern Tokyo) and appointed Razan's grandson Hayashi Hōkō (1644-1732) as its head, a position that the Hayashi maintained within their family through the remainder of the Tokugawa period.

Outside the Hayashi family, Yamazaki Ansai (1618-82) was probably the best known Japanese spokesman for Zhu Xi's teachings. Yamazaki Ansai founded his own school, the Kimon, in which he stressed an uncompromising moral rigour in one's pursuit of sagehood, with particular emphasis on the cultivation of seriousness. Ansai also formulated his own version of Shintō called Suika in which somewhat arbitrary correspondences were drawn between elements in the Confucian metaphysic and Shintō noumena. The Kimon was by far the most successful private academy in Japan devoted to the teachings of Zhu Xi, though Ansai's attempt to reconcile Confucianism with Shintō and his tradition of moralism meant that the academy was never without its share of controversies.

Zhu Xi's teachings were responsible in Japan for a complex intellectual legacy which included humanism, rationalism, ethnocentrism and 'historical mindedness'. The humanism was related to Zhu Xi's conviction that the responsibility for maintaining the delicate balance that lay at the heart of both the individual and the cosmos lay squarely on the shoulders of human beings. The rationalism emerged in response to the Confucian belief that the world and all its phenomena were ultimately understandable, and even though the understandings might vary among Confucian teachers, the mere assumption of intelligibility encouraged a broad range of scholarly enquiries. The ethnocentrism was related to the fact that Confucians in China had traditionally regarded their own heritage and tradition as paramount, and so despite the fact that Confucians in Japan were at times regarded as excessively Sinophilic, Japanese Confucians often manifested patriotic qualities that were in no way secondary to those of their Chinese counterparts. Finally, the historical mindedness derived from the fact that Confucianism taught that all examples or virtue and vice necessary to demonstrate the essentially self-correcting property of historical principles might be found within the copious records of the past.

Furthermore, with the ontological and epistemological shift that Confucian philosophy provoked, one observes the transformation of a host of related fields of study of which Shintō provides perhaps the best example (see Shintō). Shintō had heretofore existed in comfortable equilibrium with Buddhism and had reconciled its teachings to Buddhism, but from the very start of the Tokugawa period, and with increasing frequency through the seventeenth century, one observes Shintō scholars seeking to refashion their theologies, dropping Buddhist epistemes and replacing them with Confucian vocabulary and assumptions. Many Confucian scholars in Japan, in particular those identified with the Zhu Xi tradition, were for their part similarly impelled to reconcile the 'truths' of Confucian philosophy with the traditional spirituality of Shintō.

In China the principal challenge within the Confucian tradition to the teachings of Zhu Xi was identified with the teachings of the scholar and celebrated general Wang Yangming (1472-1528) who identified the mind as the seat of original goodness within human beings. His philosophy emphasized what he styled the 'unity of thought and action' whereby, for example, the concept of filial piety was regarded as the genesis of filial action, and filial action was regarded as the completion of the filial impulse. Further, by emphasizing the mind's intuitive understanding of goodness, Wang Yangming and his followers de-emphasized the study either of texts to glean their truths or the physical world to plumb its principles. This philosophy, known as Yōmeigaku (literally 'Yangming studies') in Japan, had proponents there during the seventeenth century, of whom the two best known were Nakae Tōju (1608-48) and Kumazawa Banzan (1619-91), who was also celebrated as a reformer of the *samurai* class. Nonetheless, Yōmeigaku did not command a large audience in Japan until the closing years of the Tokugawa period when its idealistic orientation proved attractive to a wide range of politically activist reformers.

In Japan, however, a more significant Confucian challenge to Zhu Xi's teachings was mounted by those scholars whose teachings are collectively referred to as Ancient Studies (*kogaku*). Though the various scholars identified

with Ancient Studies differed significantly, they shared the premise that if truths representing a Way lay within the core texts of ancient Confucianism, then those truths might be better apprehended through the study of the ancient texts themselves, than by reading the exegesis on those texts written centuries later by scholars like Zhu Xi. Ancient Studies is said to have begun with the writings of Yamaga Sokō (1622-85), who described how he came to understand that his 'misunderstandings' derived from his reliance on Chinese commentaries, but that once he turned directly to the writings of Confucius and the other ancient sages, he finally understood their message. A similar approach was used by Itō Jinsai (1627-1705) and his son Itō Tōgai (1670-1736) whose school, the Kogidō (Hall of Ancient Meaning), represents the first financially successful private Confucian academy in Japan.

The most prominent of the Ancient Studies scholars, however, was Ogyū Sorai (1666-1728). Where other Confucian scholars in Japan had accepted naturalist ontologies and without exception regarded the sage as a figure of great wisdom who discovered the Way and its truths, Ogyū Sorai applied a historicist perspective to this question. Sorai regarded the Way as a 'comprehensive term' which included those laws, rituals and other practices that ancient rulers invented and applied successfully to rectify the ills of their own ages. If, Sorai argued, the ills of the present are to be similarly rectified, then one must account for the altered circumstances that prevail in another time and place for the application of this redefined 'Way' to be successful. Further, the manner in which one learns of the ancient Way is through the study of ancient texts in which the Way is encoded, but since the words that comprise those texts have themselves changed over time, Sorai insisted that his students become proficient in historical linguistics. Known as the Ken'en, the Sorai school is believed to have been the most popular of all Confucian schools in Japan through the mid-eighteenth century.

Confucian philosophy influenced the Tokugawa polity in a variety of ways. Perhaps the most conspicuous was the tendency within the society to see itself as comprised of four classes with *samurai* (*shi*) at the top, followed by agriculturalists, artisans and merchants in that order. Notwithstanding the fact that this ideal came to deviate significantly from the mercantilist realities of urban Japan, this paradigm was of Confucian origin in China and represented the attempt to identify the Japanese samurai class with the scholar-bureaucrat (*shi*) class of China. Similarly, the study of Confucian philosophy came to be of vocational advantage to *samurai* who found their martial skills no longer as useful to a society that remained essentially at peace for over two centuries. In this way, many *samurai* became sufficiently expert in Confucian philosophy to themselves become instructors of the subject within their own private academies. One benefit that Japanese society later derived from this development in the study of Confucian philosophy was a well-developed literate and patriotic managerial class available to serve the nation in its later modernization efforts.

Throughout the seventeenth and early eighteenth centuries, there was no academic tension between the study of Confucian philosophy and the study of subject material from the native tradition, but during the eighteenth century, scholars devoted to the study of things Japanese criticized Confucians in Japan for not only neglecting but even harming their own tradition by engaging in the study of a 'foreign' humanly constructed Way. Notwithstanding that this argument both applied and owed more to the followers of Ogyū Sorai than other Confucian schools, one does observe a new tension between Confucian and nativist pursuits during much of the eighteenth century, a tension which is essentially overcome through the reconvergence of these academic fields during the nineteenth century.

The scholars who most successfully represented this synthesis of Confucian and native ideals were largely identified with the Mito domain. The *daimyō* (or lords) of Mito had aggressively sponsored scholarship on Japanese history and ancient classics since the seventeenth century, devoting as much as one-third of the domain's revenue to sponsored research. As the shortcomings of the Tokugawa state became steadily more apparent, it was Confucian scholars from Mito who sought to identify within the Japanese traditions paradigms of such Confucian virtues as loyalty and filial piety, arguing that the study of Japanese history revealed those virtues to have existed in more persuasive forms in Japan than in China.

In the same manner, one can observe within Japanese Confucian philosophy itself the fracturing of Confucianism into competing schools in the eighteenth century, followed by the nineteenth-century resurgence of certain syncretic tendencies within the Confucian tradition. For example, even though the popularity of the various Ancient Studies schools of Confucianism contributed unprecedented pluralism and intellectual vitality to Confucian philosophic circles, the often contentious relations between schools represented a scholarly atmosphere

that some regarded as indecorous. Alarmed over what it regarded as an unhealthy degree of intellectual heterodoxy within Confucian circles generally, and the Hayashi school in particular, the Tokugawa government issued a directive in 1790 ordering the head of the Hayashi school to maintain greater fidelity to the teachings of Zhu Xi. This concern with philosophical orthodoxy was, in fact, just one way in which the government at this time was attempting to return to those ‘fundamentals’ which it believed to have been responsible for the success of the Tokugawa state in the seventeenth century.

Numerous Confucian philosophers of the late Tokugawa regarded what they perceived to be the ills of their age as related on the one hand to this contentious intellectual atmosphere and on the other to an excessive tendency toward activism on the part of other Confucians. These scholars sought solace in and believed that they might affect reform through eclectic approaches to the exegesis of traditional Confucian texts. Their scholarship lacks the vitality of that evidenced within Confucian circles of the first half of the Tokugawa period, and in most studies they have been overshadowed by their more activist contemporaries; yet their scholarship provides compelling evidence of the degree to which Confucian philosophy represented an intellectual sanctuary for many late-Tokugawa intellectuals.

4 Confucianism in modern Japan

Confucian philosophy contributed to the rationales used by ideologues who led the Meiji Restoration of 1868. For example, the slogan ‘Loyalty to sovereign (*chū*) and filial piety (*kō*) are one’ argued that Confucian loyalty to one’s lord, here understood to mean the emperor, was no less fundamental than those Confucian virtues that bound family relationships, of which filial piety was always regarded as the foundational virtue. Similarly, the slogan *taigi meibun* used Confucian vocabulary to argue that there was a correct fixed position for each person within an essentially immutable social order, and when each person performed their duty the social order was harmonious. Both of these slogans reflect the fact that Confucianism generally appears both during the Meiji Restoration and thereafter primarily in terms of its social and political ethics, with the emphasis on individual duty and responsibility.

During the Meiji period, when much that was traditional in nature was overwhelmed by the rapid reforms, Confucian philosophy demonstrated remarkable resiliency as its vocabulary and reasoning were used in various ways to reinforce an understanding of the Japanese polity as a quasi-family state. This is particularly evident in the Imperial Rescript on Education promulgated in 1890 under what is believed to be the influence of the Meiji emperor’s Confucian tutor, Motoda Nagazane (1818-91). The Rescript speaks of the Japanese people as subjects who are ‘united in loyalty and filial piety’, representing the ‘fundamental character’ of the Japanese empire and the foundation of its education. Other Meiji scholars such as Nishimura Shigeki (1828-1902) sought to reconcile the ‘truths’ of Confucianism with the ‘truths’ of Western culture and civilization, often under one or another variation of the binary theme ‘Eastern ethics and Western science’.

Despite the fact that Confucian philosophy has been alternatively vilified in Japan as synonymous with all that is old-fashioned and hence bad, and lionized as embodying all that is noble and of enduring value within the traditional culture, it is evident that a number of assumptions that are characteristic of Confucian ontology and ethics remain widely accepted within present-day Japan. Conspicuous among these are the assumptions that there are enduring metaphysical principles that undergird the physical world, and that these principles have a self-correcting quality. For this reason, a fundamental moral optimism is justified. These principles have an analogue within human beings in the form of an originally good disposition which is instinctively capable of moral and ethical behaviour. Human relations are similarly governed by enduring principles, where these relations tend overwhelmingly to be vertical in character with clear superiors and subordinates. One’s most important relationships are those within the family, and it is these domestic relationships that provide the training ground for the more complex relationships one enters into outside the home. Since both the material world and the realm of human society are governed by identical principles, all phenomena and things, all persons and other creatures are interrelated, making it possible to gain insight into the whole from mastery of any of its parts.

There are other ways in which Confucian philosophy is said to have contributed its legacy to the intellectual and social fabric of contemporary Japan. Most prominent among these are the assertions that the high value attached to education, the high levels of respect accorded to those in authority, the reverence shown toward one’s ancestors and forebears, and the willingness to subordinate one’s own interests to the interests of larger collectivities in

modern Japan are all attributable to the influence of Confucian philosophy. More recent scholarship, however, has tended to see these tendencies as features that either have antecedents in pre-Confucian times or that can be traced to other influences, though there is broad agreement that Confucian philosophy at the very minimum contributed to the reinforcement of these values, each of which remains prominent in modern Japan.

Confucian philosophy, Korean

Confucianism came to Korea in the late fourth century AD. While Buddhism, which had arrived at the same time, was for centuries the central spiritual and intellectual tradition of Korea, Confucianism was viewed as largely limited to the world of government functionaries. In China during the Song dynasty (979-1279) a creative Confucian movement revitalized and reshaped the tradition, giving rise to what Western Scholars call 'neo-Confucianism'. By the end of the fourteenth century neo-Confucian learning had penetrated deeply among young scholar-officials in Korea, who used it as a lever against the deeply entrenched Buddhist establishment. In 1392, in history's only neo-Confucian revolution, a new dynasty was founded in Korea. The Chosôn dynasty (1392-1910), ruling a country smaller in scale and more centrally unified than China, was to make Korea the most (neo-) Confucian of all East Asian societies.

The scale, control, and temper of Korean society had important consequences for the development of the neo-Confucian tradition. In China the Cheng-Zhu school of neo-Confucian thought held privileged status as the orthodox standard for the all-important civil service examinations. Zhu Xi (1130-1200) was the great creative synthesizer of this school and its foremost authority, but his synthesis drew especially upon the work of the Cheng brothers. The Cheng-Zhu school was rivalled and even eclipsed in popularity later by the school of Wang Yangming (1472-1529), whose more Zen-like approach also found great favour in Japan. Korea, in contrast to both China and Japan, remained almost exclusively devoted to the Cheng-Zhu school.

This exclusive and intensive development of the Cheng-Zhu school of neo-Confucian thought is the most generally distinctive characteristic of Korean neo-Confucianism. When the thinkers of a culture devote themselves for centuries to a single complex body of learning, as was the case for example with Aristotle and medieval Europe, the result is a mode of philosophical discourse described as 'scholasticism'. Scholastic philosophy is renowned for the intricacy and closeness of its argumentation, though this may be an obstacle for the outsider for whom it is often difficult to recapture the intense and absorbing vision which inspired major controversy about seemingly minor differences. Korea, with its exclusive cultivation of Zhu Xi's complex synthesis, produced the most scholastic version of neo-Confucian thought. The writings of scholars or scholar-officials of note were commonly collected and published after their death, so the centuries of 'collected works', written in literary Chinese, are a vast resource in which the twists and turns, the problems and potentials for development in the Cheng-Zhu school are examined with unequalled thoroughness.

To understand the particular contribution this Korean scholasticism made to neo-Confucian thought one must be aware of the scope and complexity of Zhu Xi's synthesis. The intellectual culture within which the Confucian revivalists of the Song dynasty worked had for seven or eight centuries been predominantly shaped by Daoist and Buddhist influences, so the questions in their minds as they returned to the Confucian classics included dimensions neglected by more traditional Confucianism. Read with new eyes, an entirely new level of meaning was uncovered in the ancient texts: they discovered a Confucian foundation for the meditative cultivation of consciousness that had been a particular strength of the Buddhists, and to frame it and provide an account of sagehood equal to Buddhist talk of enlightenment, they found a complete metaphysical system, a Confucian version of the kind of thinking that had been elaborated mainly under Daoist auspices. Thus Zhu Xi's synthesis knit together not just disparate thinkers of the Song dynasty, but contemporary questions with texts well over a thousand years old. It incorporated Daoist metaphysics with Buddhist meditative cultivation in a new structure with Confucian moral values and social concerns at that structure's core. Implicit in this was the conflation of the distinctive world views of India, the origin of Buddhism, and China. This has important metaphysical consequences, for the central paradigm for Indian reflection on the nature of existence was consciousness, while for the Chinese it was the image of a single living physical body.

A synthesis of this scope cannot be a seamless whole, though the conceptual system with which Zhu Xi knit it together achieved a remarkable degree of verbal consistency. This, in fact, is where Korean neo-Confucian thought makes a special contribution. For it is at the seams, where differences and tensions inherent in a synthesis are conceptually masked, that the kind of problems occur that become the source of endless scholastic controversy. Korean neo-Confucianism contains two such controversies; each has occupied minds for centuries. Though the points being debated resist any ultimate solution, the disputes themselves disclose the creative tensions

at the heart of Zhu Xi's synthesis.

The first of these controversies arose in the middle of the sixteenth century and decisively shaped the intellectual agenda for the remainder of the Chosôn dynasty. The protagonists in the controversy, Yi Hwang and Yi I, are the two most famous names in Korean thought, and allegiance to each became the central dividing line of Korean neo-Confucianism. Known as the 'Four-Seven Debate,' this controversy is the most famous philosophical dispute in Korean history. On the surface it involves the question of feelings and how they arise. Some feelings, such as commiseration or shame at doing evil, seem spontaneously human and correct, while others, such as fear, anger, or pleasure, seem more questionable. Are there then two kinds of feelings that arise from different sources? The question is of great philosophical importance, because ultimately it discloses tensions at the heart of the dualistic monism/monistic dualism which is the fundamental structure of Zhu Xi's metaphysical system.

The second great controversy arose among followers of Yi I in the early eighteenth century. Neo-Confucian metaphysics views the entire universe as possessing a single nature, which is manifested differently at different levels of existence due to the differing capacities of the concrete, psychophysical component of various sorts of creatures. The Horak controversy swirled about the question of whether the fundamental or 'original' nature of things is the same or different. The fundamental nature is normative, and it would be absurd to say the norm for a cow is the same as for a human; but the fundamental nature is fundamental and normative precisely because it is considered as anterior to the limitation/distortion of the imperfect psychophysical component. How then can it be considered as differentiated into cow and human? Pulling at these seemingly verbal loose ends leads again deep into Zhu Xi's metaphysics, revealing between its Indian and Chinese (Buddhist and Daoist) motifs tensions which come to a focus more clearly here perhaps than anywhere else in neo-Confucian thought.

1 Historical development

Neo-Confucianism has dimensions similar to Marxism in Western thought: that is, although it can be considered as a philosophical system its scope includes the practice of government, social structure and relationships, and the individual's way of life. The object of the life of the mind is not abstracted as 'truth,' but is integrated with the whole of life: Confucian thought aims beyond intellectual apprehension at the actual practice of a full and integral human life in a harmonious, well-ordered society. (see Confucian philosophy, Chinese; Neo-Confucian philosophy).

Thus the neo-Confucian revolution that inaugurated the Chosôn dynasty in 1392 was also a social revolution. Energies for the first century were largely absorbed in institution building and reform of unacceptable but deeply rooted custom such as matrilocal marriages. Contrary to Confucian theory, Korean society maintained its aristocratic structure, but the Korean aristocracy (*yangban*) in other respects became highly orthodox, correct adherence to neo-Confucian norms becoming a mark of their social distinction. The aristocratic social structure also had the effect of making the Korean ruler much more a first-among-equals, much more subject, as orthodox Confucian theory prescribed, to the remonstrance and persuasion of his ministers than was the case in Ming or Qing-dynasty China.

Towards the end of the first century, remonstrance, the right of government officials to object, criticize, and offer contrary advice to superiors and particularly to the ruler, became a central and bloody issue. Zealous Korean neo-Confucians had enshrined the right to remonstrance in three government ministries, and when these acted in concert they were able to bring the government to a standstill: they could effectively thwart the king and his highest ministers, always on grounds framed in the language of lofty Confucian moral principles. The result of this systemic tension was a series of purges from the end of the fifteenth to the middle of the sixteenth centuries; the purged were the remonstrating officials, who paid with their lives or with exile when the throne and high ministers were pushed beyond the limit. These 'literati purges' left a deep imprint on the Korean neo-Confucian tradition. All Confucian learning was supposed to be for the sake of character formation, but as the established core of civil service examinations it was also the way to get ahead, and the way to secure a high reputation. In the Cheng-Zhu school a movement by earnest scholars who focused on self-cultivation and despised the ambitious motives of 'worldly Confucians' appropriated for itself the label '*daoxue*', (in Korean *tohak*), 'the learning of the true Way'. The effect of the early history of purge and martyrdom was to give special luster to the *tohak* dimension of the tradition, making it a predominant feature in the lives and thought of virtually all major Korean neo-Confucians.

The record of the development of neo-Confucian thought during this early period is somewhat sparse. The major focus initially was on institution building, while the philosophically interesting aspects of neo-Confucian thought are most closely linked with spiritual self-cultivation and its metaphysical framework. Those most likely to produce writings of interest were thus also the most likely purge victims, and what they may have written is lost. What we possess reflects the diversity and unevenness one might expect: during this period Cheng-Zhu orthodoxy had not fully settled in, nor was there a complete and systematic grasp of the integrated whole of this school's complex synthesis. The most famous name of the period, Sô Kyôngdôk (1489-1546), espoused a monism of material force (*ki*; in Chinese *qi*) similar to that of the early Chinese neo-Confucian, Zhang Zai (see Qi). Sô has a great reputation for independence and originality, but unfortunately what remains of his writings is not enough to give a very adequate picture of his ideas. Others, such as the famous martyr of the 1519 purge, Cho Kwangjo (1482-1519), reflect a situation in which those most involved with the self-cultivation side of the tradition had a very inadequate grasp of the delicate balance between theory and practice, study and meditation, that characterizes the Cheng-Zhu school. Cho's writings perished with him, but his students, we are told, often spent the day sitting in meditation rather than studying.

It is generally agreed that a full, balanced, and mature grasp of Zhu Xi's complex synthesis first came with the work of Yi Hwang (1501-70). He and a thinker of the next generation, Yi Yulgok (1536-84), are considered the foremost neo-Confucian philosophers of Korea. Particularly important was the Four-Seven Debate, initiated between Yi Hwang and Ki Taesûng (1527-72) and continued by Yi Yulgok and Sông Hon (1535-98), with Yi I taking up the position advocated by Ki Taesûng (see §§3-4). The debate had the effect of permanently dividing the neo-Confucian intellectual world of Korea into two major schools professing allegiance to Yi Hwang and Yi Yulgok, a division further complicated by complex regional and factional ties as time progressed.

Invasions first by the Japanese under Hideoshi and then by the Manchus devastated the country. The seventeenth century is remembered principally for extreme factional division and conflict by neo-Confucians in government and for the development of a rigid, orthodox tone that caused the persecution of several scholars labelled as 'heterodox' because they questioned elements of Cheng-Zhu learning.

Zhu Xi's synthesis was sufficiently vast, however, to permit major divisions and significantly different interpretations within it. The Yi Hwang-Yi Yulgok split was already evidence of this, and in the early eighteenth century the Horak controversy confirmed it. Named for the regions associated with the principle figures in the debate, the Horak controversy caught the attention and drew in major thinkers of the eighteenth century and beyond. Its participants were all followers of Yi Yulgok, and in some ways, as will be discussed below, the controversy could be considered a final working through of problems deeply embedded in Yi Yulgok's insistence on philosophical consistency in handling the Four-Seven question.

The eighteenth and nineteenth centuries are also celebrated by Korean intellectual historians for the rise of *sirhak* or 'practical learning', a broad and disparate movement among some neo-Confucian scholars towards focusing their scholarly efforts on more concrete issues of political, social and economic concern, bringing the borderless discourse of neo-Confucian thought more within the confines of actual life on the Korean peninsula. The movement historically did not develop a cohesive self-consciousness, and the label '*sirhak*' was applied to it by twentieth century historians, who saw in it the indigenous development of values and types of learning that have become the essence of modernity.

Their attention has brought to light a *sirhak* dimension in a number of significant thinkers of the period, among whom the figure of Chông Yagyong (1762-1836) overshadows all. A true polymath, in addition to extensive writing on practical affairs his works include a voluminous review of the changing interpretation of the Confucian classics over the centuries and a critique of Cheng-Zhu metaphysics from a theistic perspective grounded in the most ancient classics. His restoration of a theistic Confucianism occurred under the influence of the writings of the Roman Catholic missionary to China, Matteo Ricci. The work itself is thoroughly Confucian, however, and since it was worked out by a thinker who also had mastery of the Cheng-Zhu synthesis it is possibly the most thoroughgoing and systematic theistic philosophy produced by a Confucian thinker. In his day Chông had no significant intellectual heirs, but he may well be the most studied thinker of the Chosôn dynasty.

2 The centre of philosophical reflection

Among the East Asian neo-Confucian traditions what is most distinctive about Korea is the depth and continuity of its commitment to the orthodox Cheng-Zhu school. Thus even those like Chông Yagyong who struck out in new directions did so with a deep grounding in Cheng-Zhu thought. For the vast majority of thinkers the fundamental truth of Zhu Xi's vision was a given, and the essential task of every generation was to understand how their particular problems and insights fit into, or 'already were', the original meaning intended by Zhu Xi or the ancient authorities such as Confucius and Mencius as interpreted by Zhu Xi. Over four centuries of Korean reflection in this mode served to develop both the potentialities and the problems inherent in Zhu Xi's synthesis to an unprecedented degree. Korean insight in this respect is captured particularly in the two great controversies mentioned in §1, the Four-Seven and Horak debates.

Both debates focus on the same general area of neo-Confucian thought, *sôngnihak* (in Chinese, *xinglixue*), the study of the nature (*sông*) and principle (*i*) (see Xing; Li). It is no accident that the most complex and philosophically interesting controversies occur in *sôngnihak*, for it is the systematic nexus of every area of neo-Confucian thought: here converge what the West would call metaphysics, philosophy of man, psychology, ethics and ascetical theory or spiritual practice. The motive of Confucian, Daoist and Buddhist thought alike is the full realization of human potential, which demands self-cultivation. But self-cultivation involves an implicit or explicit metaphysical framework, which is necessary to understand in what the full realization of human potential may consist (see Self-cultivation, Chinese theories of). Buddhist meditative cultivation techniques assumed a monistic background. Huayan Buddhism used the indigenous Chinese term *li* (in Korean, *i*, meaning 'truth', 'rationale', 'principle' or 'pattern') to convey this monistic 'Buddha nature', the ultimate single reality of all phenomenal existence. Chan (Zen) Buddhism focused less on such intellectual formulation and stressed instead the direct and immediate realization of this as the reality of one's own and all being (see Buddhist philosophy, Chinese; Buddhist philosophy, Korean). Neo-Confucians, in close touch with this background, were aware of the importance of techniques of cultivating consciousness, but wanted nothing of Buddhist monism; thus they sought a more concrete metaphysics with a more secure grounding in phenomenal reality. Their remedy was to pair *i* with another traditional term, *qi* (in Korean, *ki*), the animating 'life force' of body and psyche and, philosophically, the very 'stuff' of the universe (see Qi). In its most coarse, turbid and condensed form, *ki* thus accounted for the concreteness of the divisible world the West knows as 'matter'; but in its original, pure and rarified condition it is also the stuff of psyche and mind, embracing the characteristics the West incorporates in terms such as 'spirit' and 'soul'.

In neo-Confucian metaphysics, *i* is made concrete and existential through its embodiment in *ki*. The focal point in its spectrum of meanings also shifts somewhat: as a stand-in for Buddha-nature, *i* was more on the side of 'ultimate truth', while in the neo-Confucian context its ancient connections with pattern or order are exploited in a way that makes it virtually interchangeable in many contexts with the much used *dao*, the Way, the inner pattern, the nature that structures all existence and activity. Instead of Buddhist monism, this dualism of *i* and *ki* gives us a modified, organismic monism: *i* is one, but embodied and manifested diversely through the many diverse conditions of *ki*. The many beings of the universe may thus be likened to the members of a single living body, truly different from one another and yet ultimately manifestations of a single unity beyond all name or distinctness: *i* is the single pattern or principle running throughout, while *ki* accounts for the real but not ultimate diversity.

This neo-Confucian metaphysics thus yields a very traditional East Asian organismic vision of the universe, in which every element at every level is interdependently woven together with every other in a patterned, normative whole (see Neo-Confucian philosophy). The cosmic dimensions of this tradition had found clearest manifestation in Daoism, while Confucianism had explored mainly the social ramifications; as united in neo-Confucian thought, these become respectively the framework for and the outcome of self-cultivation. The theory of self-cultivation is related to metaphysics much as epistemology is in western thought. The organismic unity of *i* solves the western problem of how distinct individuals can know 'the other', for in spite of the manifold diversity of their ways of manifesting it, all share in the same *i*. In particular, because of the high purity of the *ki* which constitutes the human psyche, *i*, the pattern of all things, is possessed in its integral fullness by the human heart-and-mind (see Xin). This means we have within ourselves the guiding pattern for appropriate responsiveness to any thing or any situation. If we are out of touch and inappropriately responsive, that is because of some adventitious factor such as an element of turbidity or coarseness in the *ki* of our psychophysical constitution which blocks or distorts our true connectedness. Neo-Confucians compared this to the way a paralyzed limb, even though connected, no longer

responds appropriately to the needs and messages of the body. The ideal sage, endowed with perfect *ki*, responds to all things with spontaneous perfection; being perfectly in touch, he need not be concerned about prolonged thought or self-discipline. Less perfectly endowed individuals, however, need both. They must follow the more laborious path, regaining their apprehension of *i* by the discipline of focused attention externally and clear calmness internally. Meditative practice, 'quiet sitting', could nurture the quiet and calm that self-possession promotes and is a means to our harmonious integration in the *i* that is our nature within and also the structure of the world without.

Sôngnihak, 'the study of the nature and *i*', thus addresses itself to the anthropocosmic core of neo-Confucian learning, where the metaphysics of the universe transmutes into a description of the working of our inner life in relation to every life situation. *I* is not only the pattern of the universe, but the ground of our psyche which prepares us to participate properly in the universe; *ki* is not only the stuff through which all things have their concrete actuality and diversity, but also the factor that distorts the potentially perfect continuity of *i* without and within. Unlike dualisms of spirit and matter which carve out a unique and special place for human beings, the challenge here is to describe all the complexity and conflict of the human heart-and-mind in continuity with the conceptual system used for all other natural phenomena. Korean neo-Confucianism pushes the limits and reveals hidden tensions in the Cheng-Zhu version of this endeavour.

3 The Four-Seven Debate

In the history of philosophy, the Cheng-Zhu metaphysics and anthropology of *i* and *ki* occupy a very special and interesting place. The patterning *i* and the concertizing, activating *ki* bring to mind the Aristotelian dualism of form and matter (see Aristotle §§11-14); but in this case, although *i* is manifested as many forms it is ultimately one form which runs through all things. Thus the universe is truly a single organic unity, rather than a plurality of formally and materially discrete beings as in the Aristotelian case. This is a monistic dualism. Recalling the Buddhist usage of *i* and the vitalistic background of the concept of *ki*, one also sees in the dualism traces of the mind-body split and the spirit-matter dualism of western thought. But here too the parallel is instructive because it breaks down: mind and body alike are comprised of *i* and *ki*, so they too are an organic continuum. As we shall see, each of the great Korean controversies pushes and tests the meaning and resources of the *i*-*ki* dualism along these lines.

The Four-Seven debate arose in 1549, and was carried out in lengthy correspondence first between Yi Hwang and Ki Taesûng, then between Yi Yulgok and Sông Hon. The central question of the debate focused on the metaphysical explanation of good and evil. In a pluralistic western context this is commonly a question of will and choice, premised on the human individual's distinctive characteristic of rationality and self-determination (see Free will; Evil, problem of). But in a culture and philosophy of organicism the question is posed in terms of response rather than choice: as seen in §2, the question of evil is more like why a limb does not respond appropriately than why individuals choose what is wrong. Hence questions of will and choice are secondary in Confucian moral discourse. Of primary concern rather are the feelings and the nature which is manifested in the way the feelings respond. In a famous classical passage, Mencius had argued that human nature is fundamentally or originally good, citing as evidence the spontaneous feelings of alarm and commiseration that arise at the sight of a dire event such as a toddler about to fall into a well (see Xing). He expanded this argument by describing four such spontaneously good feelings or tendencies: in addition to commiseration, there are the feelings of shame and dislike for evil, the tendency to yield and defer to others, and the sense of right and wrong. These innate tendencies, he said, if nurtured properly become respectively the mature characteristics of humanity, righteousness, propriety and wisdom.

The innate tendencies described by Mencius were referred to by later Confucians as the 'four beginnings', and they constitute the 'four' of the Four-Seven debate. Neo-Confucians took the four mature characteristics as descriptions of the composition of human nature, which metaphysically is equated with *i*, the normative inner pattern of all things. Concrete, actual feelings such as the Four Beginnings, are the manifestation of *i* on the level of the active, phenomenal world, the level of *i* combined with *ki*. Because *i*, the norm, is inherently good, so the feelings which manifest it are also naturally good unless imperfections in *ki*, the stuff of our psychophysical constitution, somehow interrupt and distort the way in which it is manifested.

The 'seven' of the Four-Seven debate comes from a different source, the classic *Lijing (Book of Rites)*, which

describes a list of seven feelings: desire, hate, love, fear, grief, anger, and joy. These conventional human feelings are obviously the sort of tendencies that can be either right or wrong, appropriate or inappropriate. They are the object of endless Confucian exhortations to cultivate careful attention and discernment of the movement of the feelings. The initial movement in particular is critical, for a tiny discrepancy at the beginning can become a gap of a thousand miles as things unfold.

On the level of traditional moral discourse none of this poses any special problem. The disruption of feelings and responses from their appropriate course could be accounted for by individualistic self-centredness, long identified as the root of all evil. But the special advance of neo-Confucian thought was that its new dualistic metaphysics could support a metaphysical explanation of the source of evil/disruption as well. This was of critical importance, for the description of the distorting role of *ki* with regard to the inherently perfect *i* provided a precise description of sagehood and the hinderance to sagehood, and hence an understanding of the rationale and effectiveness of approaches to self-cultivation.

In Western thought, spirit-matter dualisms, or rationality versus animal nature, set up clear value hierarchies which become the basis for explaining why it is wrong to subordinate higher values to lower. *I* and *ki*, being associated respectively with the normative and distorting roles, appear to invite a similar value discrimination. There is then an initial plausibility in suggesting that inherently good feelings such as the Four Beginnings are on the side of *i*, while more doubtful ones such as the Seven Feelings must be on the side of *ki*. This is what Yi Hwang did, almost incidentally, in the course of going over a diagrammatic treatise by another scholar. However, Ki Taesûng, a younger contemporary, reproached him. *I* and *ki* are absolutely interdependent, have no separate existence, and cannot separately be the source of different kinds of feeling; rather, he argued, there is really only one kind of feelings, for all feelings arise in precisely the same way, *i* being the formative source and *ki* the element of concrete actualization. There is, he said, actually no real (metaphysical) distinction between the Four Beginnings and Seven Feelings: the Seven Feelings are a general term for all human feelings, and the Four Beginnings are just a subset, singling out feelings when they are appropriate. Yi Hwang fought for a real distinction, even finding a passage in which Zhu Xi himself paired the Four Beginnings with *i* and the Seven Feelings with *ki*. Finally he came up with a formula that attempted to take full account of the inseparability and interdependence of *i* and *ki* and at the same time could support some feelings which are inherently more whole and human than others: in the case of the Four Beginnings, he said, *i* gives issuance and *ki* follows; in the case of the Seven Feelings, *ki* issues and *i* mounts it.

Ki Taesûng eventually yielded to Yi Hwang's formula, but after Yi Hwang's death the debate was resurrected when Yi Yulgok's friend Sông Hon read Yi Hwang's treatise in conjunction with some similarly dualistic remarks by Zhu Xi and was persuaded. Yi Yulgok, perhaps the most brilliant and systematic philosophical mind produced by the Korean neo-Confucian tradition, countered forcefully that such extreme dualism was absolutely wrong. *I* and *ki* could not vary their role and relationship as if they were two independent entities; in the metaphysics of the cosmos, he argued, it was always *ki* that was in the concrete issuing role and *i* 'mounting it' as the formative pattern that made things be and act as they did. If this was the cosmic case, it could be no different when it came to the human psyche. The dualistic expressions frequent in Zhu Xi and other authoritative sources should be understood appropriately in their moralizing context, but not transformed into a metaphysical dualism that would disrupt the delicate one-but-two, two-but-one perfect interdependence and complimentarity of *i* and *ki*.

The Korean neo-Confucian intellectual world subsequently split between followers of Yi Hwang and Yi Yulgok; infrequent thinkers attempted various sorts of syntheses, but the problem has never been resolved. On Yi Hwang's side are the dualistic phenomena common to the moral life; self-cultivation above all was the controlling factor in Yi Hwang's thought. However, Yi Yulgok has the appearance of greater philosophical consistency and rigor; he truly removed insupportable ambiguities in Zhu Xi's system and brought it to a new level of coherence.

4 The Four-Seven Debate (cont.)

What do we learn from this controversy? The two positions and the unresolvable dispute offer a unique window on the Cheng-Zhu philosophical enterprise. Yi Hwang is a faithful reflection of the motivation behind the neo-Confucian project, which is ultimately to bring about good character formation and proper order in society and the world. Yi Yulgok shows us the most careful philosophical crystalization of the deep East Asian assumption that there is no final distinction between humanity and the rest of existence: we are an integral and organic part of

the universe. In the West morality has often been treated as a uniquely human phenomenon, something that marks us off from the rest of the world. As seen through the frame of the Four-Seven debate, the challenge taken up by neo-Confucian metaphysics is whether a philosophy of organic unity can adequately account for the phenomena of human moral experience, particularly the conflicting tendencies to which we are subject and which seem less evident in the life of the rest of nature.

In its historical context the Four-Seven debate concerns the adequacy of the neo-Confucian incorporation of Mencius' explanation that human nature is good. The deep issue is, how can the normative human nature (*i*) be considered a dynamic element assisting in this process? Health and life are normative but not abstract: the body fights for health, injured trees and plants heal themselves if given time. Mencius used such examples in a more than metaphorical sense: he saw human psychic or moral life as part of the same natural system with a similar dynamism, and the neo-Confucians certainly meant to carry forward this vision. Equating the nature with *i*, the normative of each and all things, seemed to be a metaphysical version of Mencius' view. But *ki*, its counterpart, raises questions: it was introduced not only to insure an objectively real world versus the Buddhist monism of consciousness, but also to objectify the moral problem. The latter was perhaps the more important issue in Confucian eyes: Buddhism claimed ultimately to transcend the dualism of good and evil, and neo-Confucians were bitterly critical of the anti-nomian potential in such views. With its degrees of coarseness or turbidity, *ki*, by contrast, objectifies the problem of moral distortion. The neo-Confucian elaboration of a systematic philosophical explanation for a source of evil within the human constitution that does not negate the inherent goodness of human nature was a great triumph. But the solution may have succeeded too well, for the turbidity of *ki* in the psychophysical constitution seemed to put a formidable barrier between the person and the kind of spontaneously good tendencies of which Mencius spoke. In China this resulted in the radical split in which Wang Yangming simply equated the human heart-and-mind with *i* and thus opened the way to immediate intuition and spontaneous perfection in stark contrast to the kind of prolonged book learning and rigorous ascetical practice demanded in the Cheng-Zhu approach. The orthodox followers of Zhu Xi claimed this amounted to another form of Chan (Zen) Buddhism, but Wang's school was nonetheless immensely successful in China and Japan, although not in Korea.

The position worked out by Yi Hwang is an answer to this problem that remains totally within the Cheng-Zhu tradition; in comparison, the Wang Yangming solution appears an extreme and perhaps unnecessary alternative. By granting *i* the possibility of some kind of initiative to set the current in the proper direction before the disrupting influence of *ki* could take over, he was providing grounds for the spontaneous and appropriately human responsiveness Mencius had spoken of: '*I* gives issue and *ki* follows.' But the price is emphasizing the dualistic potential in Cheng-Zhu thought, for perfect complimentarity demands *ki* alone have such a concrete actualizing function. This was Yi Yulgok's objection; but in demanding that Yi Hwang's formula for the more dubious Seven Feelings, '*ki* gives issue and *i* mounts it', be the only one, he is hard pressed to really save Mencius. It would seem that if imperfect *ki* is in at the origin of all feelings in exactly the same sort of way, then the normative goodness of *i* is a mere abstraction, not something that is manifest in the actual tendencies of our inner life. The only way the perfection of *i* can spontaneously manifest in the phenomenal world would seem to be through the agency of perfectly pure *ki*.

The tightness of Yi Yulgok's consistent insistence on the absolute complementarity and interdependence took Cheng-Zhu thought to a new level of systematization. At the same time, the question remains as to whether this systematization could settle the kind of issues solved by Yi Hwang's more dualistic approach. The real test of his system came more than a century later with the Horak debate.

5 The Horak Debate

The Horak debate arose in the early decades of the eighteenth century among scholars belonging to Yi Yulgok's school of thought. Once launched, it was the source of philosophical debate down to the twentieth century, second only to the Four-Seven debate in length, notoriety and intellectual importance among Chosôn dynasty neo-Confucian controversies. Its chief protagonists were Han Wônjin (1682-1751) and Yi Kan (1677-1727). Both were students of the same prominent master, Kwôn Sangha, and both at different times held the prestigous position of Royal Lecturer, reflecting their recognition as leading scholars of their time. The debate takes its name from the geographical regions with which the major participants were associated: the 'ho' group was centred in Ch'ungch 'ôngdo and supported the position of Han Wônjin, while the 'Nak' scholars who supported Yi Kan hailed mainly

from Kyônggido.

The Horak controversy began on grounds that can be considered in some ways a continuation of the Four-Seven debate, driving Yi Yulgok's position to its final ramifications. However, in addition to pushing to the ultimate the question of a non-dualistic metaphysics of *i* and *ki* and its meaning for self-cultivation, the controversy took a new turn that brought out hidden tensions and ambiguities in the concept of *i* itself.

The Four-Seven debate pushed the issue of the ramifications of the metaphysics of *i* and *ki* for the responsive life of the heart-and-mind; the Horak debate revisited the question, but this time with a focus on how to understand the meditative practice that was an important feature of self-cultivation. After centuries of Buddhist predominance, it was natural for early neo-Confucian thinkers to assume that consciousness itself, not just moral habits and self-discipline, is a key object of cultivation. Likewise, long familiarity with meditative discipline affected the way they understood the paradigmatic yin-yang pattern of alternating activity and quiet as it applied to consciousness: quiet was taken to mean not just relative inactivity, but absolute inactivity, that is, the condition of objectless consciousness familiar to trance meditation. Thus classical references to a condition before the feelings were aroused became a warrant for a meditative discipline known as 'quiet sitting': the mind resting in objectless consciousness, in this view, is but the natural compliment to the mind actively engaged with some sort of object. Both of these conditions should have their appropriate role in self-cultivation.

Just as they framed the understanding of the feelings, *i* and *ki* served to interpret the place and meaning of meditation practice. Turbid *ki* translated easily into literal psychic turbidity and tumult; clarifying and calming one's consciousness was also a matter of clarifying and calming one's *ki*. In this conceptualization there is an easy movement from the philosophical usage of the term *ki* in metaphysics to the more popular use of the term in which *ki* is the life force and the force of the feelings. What then would be the meaning of a perfectly clear, calm, objectless state of consciousness? Obviously this would be a condition of pure, undistorted unity with *i*, one's perfect nature which is, as we have seen, the formative grounds for all activity of the heart-and-mind. From this integral contact with the inner pattern for relating to all things, one might expect to gradually develop an ease and spontaneous appropriateness of one's responses in the active life; and this would also be facilitated as the practice fostered increased calm and mental focus in all areas of life. *I* as our own nature and the nature of all things lays the grounds for our appropriate interaction in all circumstances, and this practice seems highly effective as a means of removing the distortions introduced by our turbid *ki*.

One can see here the life context of the *i*-*ki* metaphysics of the neo-Confucians. Clearly, philosophical reflection here grows out of and returns to the task of spiritual cultivation. The importance in practice of *i* as not only an abstract norm but as a formative, dynamic factor in spiritual cultivation is evident. Conceptually this was captured in the idea of the 'original nature', that is, *i* as it is in itself, undistorted by the imperfection that may be present in *ki*. This again, like the Four Beginnings, is a reference to Mencius, for neo-Confucians explain that his argument that human nature is good was in fact pointing to the 'original nature' before there ever was such terminology. Of course the negative side is equally important in understanding self-cultivation. The potentially 'bent out of shape' natures of actual human beings with all the concrete reality of imperfect *ki* was conceptualized, in contrast with the 'original nature', as the 'physical (*kijil*; in Chinese, *qizhi*) nature'.

Neo-Confucians stressed that the double terminology did not mean we have two natures: the 'original nature' terminology was necessary because if one only observed the actual humans with their imperfect 'physical nature', the original perfection of *i* would not be evident. In actuality, of course, there is only one nature: the only nature (*i*) is *i* embodied in *ki*. The point of the dual terminology is that even as embodied and hence manifested in a distorted and imperfect way, the original perfection of the nature is never lost.

But what then is the point? Since all actuality occurs only in the context of *i*-with-*ki*, is the original nature anything but a way of paying lip-service to Mencius' teaching about a good human nature? The same problem we saw in the Four-Seven debate regarding the issuance of the feelings recurs here on the level of the nature, the source of the feelings. The issue is more explosive, however, for the original nature is a central aspect of self-cultivation theory: it is the dynamic base of tendencies to be cultivated and enlarged upon in activity, and meditative quiescence, the 'condition before the mind is aroused', was commonly understood as putting one in touch with the original nature.

6 The Horak Debate (cont.)

Han Wônjin ignited the controversy by remarks he made in 1707 in a short treatise on the original nature and the physical nature. As a typical follower of Yi Yulgok, his main concern was to attack dualistic misunderstandings that sometimes stemmed from this terminology. Almost incidentally, he remarked that, regarding the original nature in the condition before the mind is aroused, since it must still inhere in *ki*, one could also take that fact into account and refer to it as the physical nature. The pure perfection of the original nature could be reached only by an ‘exclusive reference’ that simply did not take *ki* into account; in reality, of course, *ki* had to be there. In quiescence, Han observed, the imperfection that might be present in *ki* could not be observed, but that does not mean it is not there.

To speak of the condition before the mind is aroused and the physical nature in the same breath was novel and provoked a storm of protest, for it deeply challenged the conventional conceptual framework of self-cultivation theory. Han’s chief opponent was Yi Kan, a man deeply steeped in self-cultivation practice who himself had experienced the problems of a turbulent consciousness and the benefits of quiet sitting. The original nature was a reality that functioned in his spiritual practice and explained his positive experience. It could not, he argued, be reduced to a mere matter of ‘exclusive reference’.

In the course of the controversy, Han’s position proved intellectually unassailable and he never modified it, even though more scholars sided with Yi Kan than with him. The logic of a consistent, non-dualistic interpretation of Cheng-Zhu metaphysics supported him: no *i* without *ki*, and hence no *i*-originated actuality without the mediation of *ki*. It was rather Yi Kan who was forced, step-by-step, to modify his position. Finally, in order to support a living contact with the original nature, he introduced the notion of an ‘original mind’, arguing that the turbidity of *ki* applied to the body but that the heart-and-mind remained essentially pure. This is the closest neo-Confucian thought approaches the mind/body dualism common in western thought; but it is a dualism of *ki*, reflecting that the stuff of both, unlike spirit/matter, is ultimately the same.

In the Four-Seven debate, Yi Hwang gave a dualistic twist to *i*-*ki* metaphysics in order to maintain the the status of Mencius’ Four Beginnings. Here Yi Kan, in a similar defence of a Mencius-inspired vision of self-cultivation, when Yi Hwang’s kind of *i*-*ki* dualism is unthinkable, must resort to a division of *ki* itself in terms of mind and body. In the overall structure and intent of Cheng-Zhu thought, the role of *i* goes beyond merely explaining formal intelligibility or grounding an intellectual norm: it is a dynamic, active force in the process of becoming a full human being, but this dynamic side threatens to cast *i* and *ki* as competitive forces in a form of dualism out of tune with the deep structure of neo-Confucian metaphysics. The language of Zhu Xi’s synthesis is continuously ambiguous, sounding in some passages quite dualistic and then, especially in more systematic metaphysical discussion, sounding non-dualistic and emphasizing perfect complementary and interdependence between *i* and *ki*. The history of these two controversies in Korea shows clearly that the ambiguities cannot be removed without a significant and creative recasting of the basic conceptual framework.

The question of the original nature in the condition before the mind is aroused led Han Wônjin into reflection on the whole question of the nature. Cheng Yi’s famous dictum, ‘*I* is one but manifested diversely’, is one of the cornerstones of the Cheng-Zhu understanding of the nature. The comprehensive one *i* of all things is the ‘Supreme Ultimate’, as Zhou Dunyi put it in his famous *Diagram of the Supreme Ultimate*. Zhu Xi’s comment reflects Cheng’s dictum: ‘Each thing has its own nature and all things are the one Supreme Ultimate’. This metaphysics accounts for the diverse manifestation of *i* whereby each thing has its own nature in terms of the varying degrees of the coarseness or turbidity of *ki*. Just as this accounts for the different degrees of intellectual and moral qualities of humans, so on a broader scale it accounts for entirely different species.

In self-cultivation discourse, it is of course the perfectly good original nature which is normative, and this led to a stress on *i*’s transcendence of the concrete limitation of *ki*: the pure and vital original nature remains unsullied, however bent out of shape it may be as manifested in a given individual. A criminal with a turbid psyche thus strives to become a better human, not a better criminal. But how does this apply to other species, similarly differentiated by the imperfection of *ki*? Is the normative, original nature of a cow the same as the original nature of a human? Han observed that according to the classics each creature should follow its nature, which implies that it is the nature *as differentiated* by *ki* that is normative: a good cow acts like a cow, not like a human.

Such reflections led Han Wônjin in 1708 to propose a novel, tripartite way of viewing the nature: (1) the nature as pure *i*, with no reference to *ki*, and hence no differentiation (the nature in this sense is unitary and ineffable); (2)

the nature as 'based on *ki*', that is, as differentiated into species but undistorted and hence normative; and (3) the concrete physical nature according to which every individual, even of the same species, is different from every other. The 'original nature', he suggested, is a differentiated norm, and this demands the distinctive second category, the nature as based on *ki*.

Han's opponents, led by Yi Kan, mocked the novel language of a nature 'based on ki' which somehow was not yet the real, concrete physical nature of an individual being. Yi held firmly to the common understanding of a unitary *i* as the 'single origin', common to and within all things, and *i* as concretely manifested in diverse individuals. With *ki* comes limitation and distortion, and hence separation from the norm; hence the original nature must be identified with the 'single origin,' and its diversity as norm must somehow be likewise contained in that.

This dispute involved the most fundamental elements of Cheng-Zhu thought, the equation of *i* with the nature of things and the use of *ki* to account for both individual (especially moral) differences and the differentiation of various kinds of creatures. It thus was pursued with intensity, but over the years no consensus could be reached. Part of the reason for this lies in a deep ambiguity in Cheng Yi's foundational proposition, '*I* is one and manifested diversely'. Is the diverse manifestation totally the consequence of *ki*? Such was the understanding of Han Wônjin, who demanded the explicit reference to *ki* to account for any kind of diversified norm. Or is *ki* the means of implementing a diversity that has its more profound source in *i* itself? Such was the understanding of Yi Kan, who treated the 'Single Origin' as a self-diversifying, normative *i*. One can find support for both of these interpretations of Cheng's dictum in the writings of Zhu Xi, but the ambiguity runs through most discourse treating of the diversification of *i* through *ki*.

The fundamental ambiguity explored in the Horak debate points ultimately to the seam by which the organismic metaphysics typified by Chinese Daoism is stitched together with the consciousness-oriented participation metaphysics (all creatures are the manifestation of One Mind) which is part of Buddhism's Indian heritage (see Daoist philosophy). *I* as self-diversifying follows the organismic paradigm of the single pattern which accounts for both the unity and the diversity of a living body; *i* as unitary but manifested in varying degrees of fullness through the varying perfection of *ki* represents a kind of monism quite different from this one-body image, bringing to mind more the One Mind which never becomes plural in spite of its manifold manifestation. Mind and body have been subtly united here in a way unparalleled by any other of the world's great traditions. Bodies are differentiated by kinds and consciousness permits of degrees. neo-Confucians utilize *i* in both these ways, explicating through it the distinctness and commonality of all things, the transcendence of a normative nature, and the universal responsiveness of human consciousness which is the highest degree of participation in *i*. As the Horak debate makes clear, this feat involves a varied conceptualization of *i*'s relationship with *ki* as the price of such an accomplishment.

Confucius (551-479 BC)

Confucius is arguably the most influential philosopher in human history - 'is' because, taking Chinese philosophy on its own terms, he is still very much alive. Recognized as China's first teacher both chronologically and in importance, his ideas have been the rich soil in which the Chinese cultural tradition has grown and flourished. In fact, whatever we might mean by 'Chineseness' today, some two and a half millennia after his death, is inseparable from the example of personal character that Confucius provided for posterity. Nor was his influence restricted to China; all of the Sinitic cultures - especially Korea, Japan and Vietnam - have evolved around ways of living and thinking derived from the wisdom of the Sage.

A couple of centuries before Plato founded his Academy to train statesmen for the political life of Athens, Confucius had established a school with the explicit purpose of educating the next generation for political leadership. As his curriculum, Confucius is credited with having over his lifetime edited what were to become the Chinese Classics, a collection of poetry, music, historical documents and annals that chronicled the events at the Lu court, along with an extensive commentary on the Yijing (Book of Changes). These classics provided a shared cultural vocabulary for his students, and became the standard curriculum for the Chinese literati in subsequent centuries.

Confucius began the practice of independent philosophers travelling from state to state in an effort to persuade political leaders that their particular teachings were a practicable formula for social and political success. In the decades that followed the death of Confucius, intellectuals of every stripe - Confucians, Legalists, Mohists, Yin-yang theorists, Militarists - would take to the road, attracted by court academies which sprung up to host them. Within these seats of learning, the viability of their various strategies for political and social unity would be hotly debated.

1 Life, works and influence

Although Confucius enjoyed great popularity as a teacher and many of his students found their way into political office, his enduring frustration was that personally he achieved only marginal influence in the practical politics of the day. He was a *philosophe* rather than a theoretical philosopher; he wanted desperately to hold sway over intellectual and social trends, and to improve the quality of life that was dependent upon them. Although there were occasions on which important political figures sought his advice and services, over his years in the state of Lu, he held only minor offices at court.

Early on, however, and certainly by the time of his death, Confucius had risen in reputation to become a model of erudition, attracting attention from all segments of society. As time passed and the stock in Confucius rose, the historical records began to 'recall' details about his official career that had been supposedly lost. Over time, his later disciples altered the wording of his biographical record in his favour, effectively promoting him from minor official to several of the highest positions in the land.

Nor does the story end there. By the time of the Han dynasty (206 BC-AD 220), Confucius was celebrated as the 'uncrowned king' of the state of Lu, and by the fourth century AD, any prefecture wanting to define itself as a political entity was required by imperial decree to erect a temple to Confucius. Gods in China are local cultural heroes who are remembered by history as having contributed meaning and value to the tradition, and of these revered ancestors, that god called Confucius has been remembered best.

Confucius was certainly a flesh and blood historical figure, as real as Jesus or George Washington. But the received Confucius was and still is a 'living corporate person', in the sense that generation after generation of descendants have written commentaries on the legacy of Confucius in an effort to make his teachings appropriate for their own times and places. 'Confucianism' is a lineage of scholars who have continued to elaborate upon the canonical texts passed on after the life of Confucius came to an end, extending the way of living that Confucius had begun.

Although the ascent of Confucius to exalted status began early in the tradition with the continuation of his work by his many disciples, it was not until Confucianism was established as the state ideology during the Han dynasty (206 BC-AD 220) that his school of thought became an unchallenged orthodoxy. By developing his insights around

the most basic and enduring aspects of the human experience - family, friendship, education, community and so on - Confucius had guaranteed their continuing relevance. One characteristic of Confucianism that began with Confucius himself, and made it so resilient in the Chinese tradition, is its porousness and adaptability. Confucius said of himself that he only transmitted traditional culture, he did not create it; his contribution was simply to take ownership of the tradition, and adapt the wisdom of the past to his own present historical moment.

Just as Confucius reinvented the culture of the Zhou and earlier dynasties for his own era, Han dynasty Confucianism drew into itself many of the ideas owned by competing schools in the earlier centuries, and in so doing, fortified itself against their challenge. This pattern - absorbing competing ideas and adapting them to the specific conditions of the time - sustained Confucianism across the centuries as the official doctrine of the Chinese empire until the fall of the Qing dynasty in 1911. In fact, an argument can be made that just as the composite of Buddhism and Confucianism produced neo-Confucianism, the combination of Marxism and Confucianism in this century has created a kind of neo-neo-Confucianism.

As recently as the Cultural Revolution (1966-76), Jiang Qing, Mao Zedong's wife, and her cohorts mounted an Anti-Confucius campaign that swept the country. The great irony of this Anti-Confucius campaign was that during this period one could not acquire a copy of the *Analects*, not because they had been banned or suppressed but because they were sold out; the entire country was put to work reading the teachings of Confucius in order to criticize them.

2 Teachings

There are many sources for the teachings of Confucius that have been passed down to us today. The most authoritative among them are the *Lunyu Analects*. (*Lunyu* literally means 'discourses'; a better translation is 'analects', coming from the Greek *analekta*, which has the root meaning of 'leftovers after a feast'.) It is probably the case that the first fifteen books of these literary 'leftovers' were assembled and edited by a congress of Confucius' disciples shortly after his death. It would seem the disciples concluded that a very special person had walked among them, and that his way - what he said and did - should be preserved for future generations. Much of this portion of the text is devoted to remembering Confucius, a personal narrative of what he had to say, to whom he said it and how he said it. The middle three chapters are like snapshots of his life-habits - Confucius never sat down without first straightening his mat; he never slept in the posture of a corpse; he never sang on a day that he attended a funeral; he drank freely, but never to the point of being confused of mind.

The last five books of the *Analects* appear to have been compiled some time later, after the most prominent disciples of Confucius had launched their own teaching careers and had taken it upon themselves to elaborate on the philosophy of their late Master. Confucius is less prominent in these chapters, yet he is referenced with more honorific terms, while the now mature disciples are themselves often quoted.

In addition to the *Analects*, the other two most important resources for the life and teachings of Confucius are the *Zuozhuan* (the Zuo commentary on the *Spring and Autumn Annals*), and the *Mencius*. The Zuo commentary is a narrative history which purports to interpret the chronicle of the court history of the state of Lu up until the death of Confucius. The *Mencius* is a text named after a disciple who elaborated the doctrines of Confucius some century and a half after his death (see Mencius), and became one of the Four Books in the Song dynasty, which were from then onwards the core of the Confucian classics (see Chinese Classics).

One thing is clear about the *Analects* and these supplementary texts: they do not purport to lay out a formula by which everyone should live. Rather, they provide an account of one man: how he cultivated his humanity, and how he lived a satisfying life, much to the admiration of those around him. The way (*dao*) of Confucius is nothing more or less than the way in which he as a particular person chose to live his life. The power and lasting value of his ideas lie in the fact that they are intuitively persuasive, and readily adaptable.

Confucius begins from the insight that the life of every human being is played out within the context of their particular family, for better or for worse. For Confucius and generations of Chinese to come, it is one's family and the complex of relationships that constitute it, rather than the solitary individual, that is the basic unit of humanity. In fact, for Confucius, there is no individual - no 'self' or 'soul' - that remains once the layers of social relations are peeled away. One is one's roles and relationships. The goal of living, then, is to achieve harmony and enjoyment for oneself and others through acting appropriately in those roles and relationships that constitute one.

Given that we all live within the web of family relationships, it is entirely natural that we should project this institution out onto the community, the polity and the cosmos as an organizing metaphor. The Confucian community is an extension of aunts and uncles, sisters and cousins; the teacher is ‘teacher-father’ and one’s senior classmates are ‘elder-brother students’; ‘the ruler is father and mother to the people, and is the son of "Heaven"’. ‘Heaven’ itself is a faceless amalgam of ancestors rather than some transcendent Creator deity (see Tian). As Confucius says, ‘The exemplary person works hard at the root, for where the root has taken firm hold, the way will grow.’ What then is the root? He continues: ‘Treating your family members properly - this is the root of becoming a person.’

For Confucius, the way to live is not dictated for us by some power beyond; it is something we all must participate in constructing. On one occasion, Confucius said ‘It is not the way that broadens people, but people who broaden the way.’ The way is our passage through life, the road we take. Our forbearers mapped out their way and built their roads, and in so doing, have provided a bearing for succeeding generations. They have given us the culture and institutions that structure our lives and give them value and meaning. But each new generation must be roadbuilders too, and continue the efforts that have gone before.

Confucius saw living as an art rather than a science. There are no blueprints, no formulae, no replications. He once said, ‘The exemplary person seeks harmony, not sameness.’ In a family, each member has his or her unique and particular role. Harmony is simply getting the most out of these differences. Similarly, Confucius saw harmony in community emerging out of the uninhibited contributions of its diverse people. Communal enjoyment is like Chinese cooking - getting the most out of your ingredients.

Confucius was extraordinarily fond of good music, because making music is conducent to harmony, bringing different voices into productive relationships. Music is tolerant in allowing each voice and instrument to have its own place, its own integrity, while at the same time, requiring that each ingredient find a complementary role in which it can add the most to the ensemble. Music is always unique in that each performance has a life of its own.

What Confucius calls *ren* - literally, ‘becoming a person’ - is the recognition that personal character is the consequence of cultivating one’s relationships with others (see Confucian philosophy, Chinese §5). There is nothing more defining of humanity for Confucius than the practical consideration of one human being for another. Importantly, *ren* does not precede practical employment; it is not a principle or standard that has some existence beyond the day to day lives of the people who realize it in their relationships. Rather, *ren* is fostered in the deepening of relationships that occur as one takes on the responsibility and obligations of communal living, and comes fully to life. *Ren* is shared human flourishing. It is the achievement of the quality of relationships which, like the lines in calligraphy or landscape painting, collaborate to maximum aesthetic effect.

Wisdom for Confucius is relevant knowledge: not knowing ‘what’ in some abstract and theoretical sense, but knowing ‘how’ to map one’s way through life and get the most happiness out of it. Happiness for oneself and for others is isomorphic; it is mutually entailing. In discussing knowledge, Confucius says that being fond of something is better than just knowing it, and finding enjoyment in it is better than just being fond of it. Confucius associates *ren* with mountains; it is spiritual and enduring, a constant geographical marker from which we can all take our bearings. Wisdom is like water, pure, flowing and nurturing. The exemplary person is both *ren* and wise, both mountain and water.

A good way to think about ‘the way’ is the notion of passage. On one occasion, Confucius observed while standing on the bank of a river, ‘Isn’t its passing just like this, never ceasing day or night!’ Life is at its very best a pleasant journey, where the inherited body of cultural institutions and the pattern of roles and relationships that locate us within community - what Confucius calls ‘propriety’ (*li*) - are a code of formal behaviours for stabilizing and disciplining our ever-changing circumstances. ‘Propriety’ covers everything from table manners to the three years of mourning on the loss of one’s parent, from the institution of parenthood to the appropriate posture for expressing commiseration. It is a social syntax that brings the particular members of community into meaningful relationships. Propriety is a discourse, which like language, enables people to communicate, and to locate themselves appropriately, one with the other.

What distinguishes ‘propriety’ from rules and regulations is that these cultural norms must be personalized, and are open to refinement. Only I can be father to my sons; only I can be this son to my mother; only I can sacrifice to my

ancestors. And if I act properly, performing my roles and cultivating my relationships so that they are rich and fruitful, other people in community will see me as a model of appropriate conduct, and will defer. It is precisely this power of example that Confucius called ‘excellence’ (*de*). Excellence is the propensity of people to behave a certain way when provided with an inspiring model.

The other side to what Confucius calls ‘propriety’ is the cultivation of a sense of shame. Shame is community-based. It is an awareness of and a concern for how others perceive one’s conduct. Persons with a sense of shame genuinely care about what other people think of them. Self-sufficient individuals, on the other hand, need not be concerned about the judgments of others. Such individuals can thus be capable of acting shamelessly, using any means at all to take what they want when they want it.

3 Disciples

Confucius was tolerant of difference. In fact, on six separate occasions in the *Analects*, he is asked what he means by *ren*, an idea that is at the heart of his teachings, and six times he gives different answers. For Confucius, instructing disciples in *ren* requires that the message be tailored to the conditions of the person asking the question. We have said that, for Confucius, persons are no more than the sum of their specific familial and communal roles and relationships, and that *ren* emerges out of the quality that they are able to achieve in cultivating them. It stands to reason, then, that to know Confucius, we do best to familiarize ourselves with his community of disciples. The Teacher can best be known by his students.

Some of these disciples come to life in a careful reading of the *Analects*. For example, although Confucius was reluctant to use the term *ren* to describe anyone, he did use it of his favourite disciple, Yan Hui, also called Yan Yuan. Living on a bowl of rice and a ladle of water, Yan Hui’s eagerness to learn and his sincerity endeared him to the Master; but he was also possessed of an incomparable character, and was so intelligent that Confucius said of him, ‘When he is told one thing he understands ten’. Although Yan Hui was some thirty years younger than Confucius, it was only him among his many disciples that Confucius saw as his equal. It is no surprise, then, that Confucius was totally devastated by the death of Yan Hui at the young age of thirty-one.

Zilu was another of Confucius’ best-known and favourite disciples. He was a person of courage and action who was sometimes upbraided by Confucius for being too bold and impetuous. When he asked Confucius if courage was indeed the highest virtue, Confucius tried to rein him in by replying that a person who has courage without a sense of appropriateness will be a trouble-maker, and a lesser person will be a thief. Confucius’ feelings for Zilu were mixed. On the one hand, he was constantly critical of Zilu’s rashness and immodesty; and impatient with his seeming indifference to book learning. On the other hand, Confucius appreciated Zilu’s unswerving loyalty and directness; he never delayed on fulfilling his commitments. Being nearer Confucius in age, Zilu with his military temper was not one to take criticism without giving it back; on several occasions, especially in the apocryphal literature, Zilu challenges Confucius’ judgment in associating with political figures of questionable character and immodest reputation. However, Confucius’ enormous affection for the irrepressible Zilu comes through the text.

Confucius was also critical of his disciples. Zai Yu, also called Ziwo, was devoted to Confucius, yet on numerous occasions Confucius criticised him roundly for a lack of character. It was as a metaphorical reference to attempting to educate Ziwo that Confucius said, ’You cannot carve rotten wood, nor can you whitewash a wall made from dry manure’.

Zigong excelled as a statesman and as a merchant, and was perhaps second only to Yan Hui in Confucius’ affections. Confucius was respectful of Zigong’s abilities, and in particular his intellect, but less impressed with Zigong’s use of this intellect to amass personal wealth. Coming from a wealthy, educated home, Zigong was well-spoken, and as such, Confucius’ most persistent criticism of him is that his deeds could not keep pace with his words. Even so, much of the flattering profile of Confucius collected in the *Analects* is cast in the words of the eloquent Zigong.

Zengzi is best remembered as a proponent of filial piety - devotion and service to one’s parents. A natural extension of this affection for one’s family is friendship. Zengzi rose to prominence after the death of Confucius as one of his leading advocates.

These and many other disciples came from around the central states of China, gravitating to the state of Lu to study

with Confucius. In spite of the sometimes severe opinions which Confucius expressed freely about them - and he admonishes almost every one of them - they were devoted to the Master, and responded to him with reverence. There is no greater proof of this enduring respect for Confucius than the fact that they had a hand in recording Confucius’ criticisms of themselves, and then went on to found branch schools based on these same criticisms to perpetuate his teachings.

4 The *Analects*: texts and commentaries

The work known as the *Analects* is mainly a collection of sayings and conversations of Confucius. In the time of Emperor Wu (140-87 BC) of the Han there were three versions of the work, the *Lulun*, the *Qilun* and the *Gulun*. In the first century BC, Zhang Yu taught a version known as *Lunyu according to Marquis Zhang*, which incorporated readings from both the *Lulun* and the *Qilun*. Zheng Xuan (AD 127-200) further adopted readings from the *Gulun*. The text that has come down to us is that of He Yan (AD 190-249) in his *Lunyu jijie (Collected Commentaries on the Lunyu)*.

The extant *Analects* is in twenty books. Of the three early versions, only the *Lulun* had twenty books; the *Qilun* and the *Gulun* both had twenty-two books, though the extra books were not identical. According to the *Xinlun* of Huan Tan (24 BC-AD 56) the order of the chapters in the *Gulun* was different and there were more than four hundred variant readings. Lu Deming (AD 556-637) of the Tang dynasty also remarked that in the *Qilun*, besides the two extra books, ‘the chapters and verses were considerably more numerous than in the *Lulun*’. Some of the variant readings were recorded by scholars before the three versions were lost and these have been collected by textual critics over the centuries, but these consist mainly of variant forms of graphs. Only a handful affect the interpretation of the text. For instance, the text of VII.17 in the traditional text reads, ‘Grant me a few more years so that I may continue to study the *Yijing* at the age of fifty, and I shall be free from major errors.’ According to Lu Deming, the *Lulun* reads *yi* (grammatical particle) in place of *yi* (meaning the *Yijing (Book of Changes)*. This can only be rendered ‘Grant me a few more years so that I may continue to learn at the age of fifty, and I shall, perhaps, be free from major errors.’ Thus the variant reading has a bearing on the substantive point whether Confucius was a keen student of the *Yijing*. Of the two eclectic versions, the *Lunyu according to Marquis Zhang* was based on the *Lulun* while incorporating readings from the *Qilun*. As for Zheng Xuan’s version, it has been the common view that this was likewise based on the *Lulun* but incorporating readings from the *Gulun*. However, this may not be the case, as there is some evidence that Zheng also adopted some readings of the *Qilun*. On their versions of the *Lunyu*, both Zhang and Zheng wrote commentaries. Zhang’s commentary was in an independent work known as *Lu Anchang hou shuo (Marquis Anchang’s Exegesis of the Lu [lun])*. Unfortunately this was lost at a very early age and we do not possess even a single quotation from it.

Zheng’s commentary was attached to his text of the *Analects*, and although the work is lost, numerous quotations, particularly through He Yan’s *Collected Commentaries*, have come down to us. In the present century a number of fragments came to light in Dunhuang and Turfan, the most notable of which is a partial manuscript copy done by a twelve-year-old schoolboy in 710 and discovered in 1969. In all, we now possess over half of Zheng’s total commentary, and this has spurred on the study of this commentary. In Bajiaolang in Ding Xian, Hebei province, a copy of the *Analects* on bamboo slips was unearthed in 1971 in a tomb of the late Western Han, consisting of over half of the whole text. The exciting part of the discovery is that the text antedates the version of Marquis Zhang, and may represent the school of the *Qilun*. Unfortunately, the publication of this text so far has not revealed any major differences.

Of the numerous commentaries on the *Analects*, only a few landmarks can be mentioned. The *Lunyu zhushu (Subcommentary on the Lunyu)* by Xing Bing (932-1010) and *Lunyu jizhu (Collected Commentaries on the Lunyu)* by the great neo-Confucian thinker Zhu Xi (1130-1200) were authoritative works for the educated reader. In the Qing dynasty, as a reaction against the neo-Confucian approach, there were new commentaries on the classics with greater philological emphasis. On the *Analects* in particular, we have Liu Baonan’s *Lunyu zhengyi (The True Interpretation of the Lunyu)*.

There is finally the question of the composition of the *Analects*. First (as noted in §2), the work as we have it was not put into the present form once and for all. The later books were likely to have been added on at a later editing. Second, within a single book, some material must have been taken from existing collections of sayings of Confucius *en bloc* and some chapters added subsequently. Finally, sayings of disciples must have been

incorporated by their own disciples to enhance their standing in the Confucian tradition. This is particularly true of Book I, in which are found sayings by younger disciples such as Youzi and Zengzi who played an important role in the formation of the Confucian tradition.

Connectionism

Connectionism is an approach to computation that uses connectionist networks. A connectionist network is composed of information-processing units (or nodes); typically, many units process information simultaneously, giving rise to massively 'parallel distributed processing'. Units process information only locally: they respond only to their specific input lines by changing or retaining their activation values; and they causally influence the activation values of their output units by transmitting amounts of activation along connections of various weights or strengths. As a result of such local unit processing, networks themselves can behave in rule-like ways to compute functions.

The study of connectionist computation has grown rapidly since the early 1980s and now extends to every area of cognitive science. For the philosophy of psychology, the primary interest of connectionist computation is its potential role in the computational theory of cognition - the theory that cognitive processes are computational. Networks are employed in the study of perception, memory, learning and categorization; and it has been claimed that connectionism has the potential to yield an alternative to the classical view of cognition as rule-governed symbol manipulation.

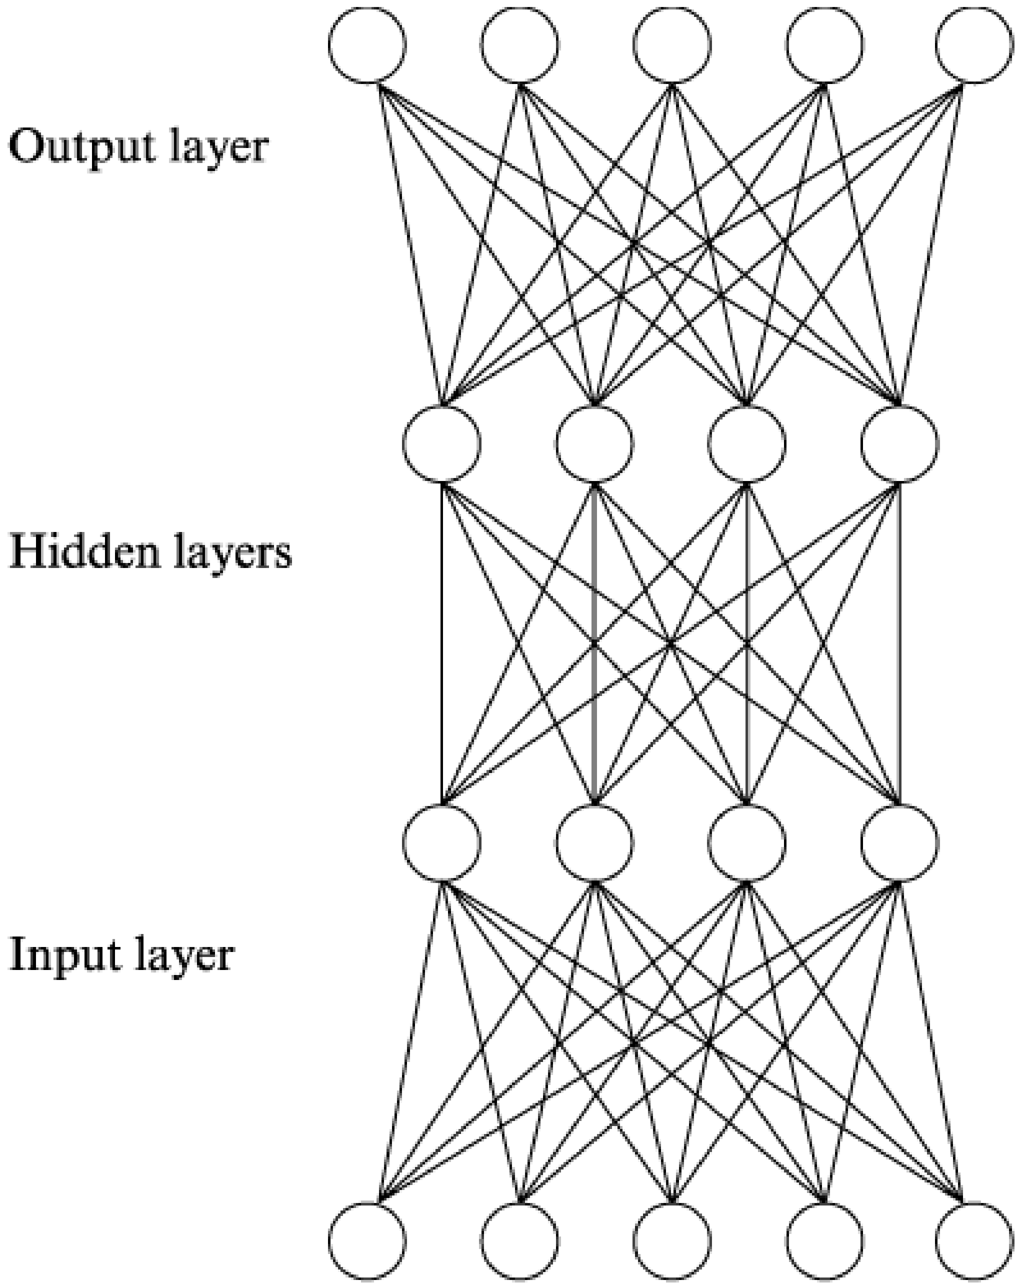
Since cognitive capacities are realized in the central nervous system, perhaps the most attractive feature of the connectionist approach to cognitive modelling is the neural-like aspects of network architectures. The members of a certain family of connectionist networks, artificial neural networks, have proved to be a valuable tool for investigating information processing within the nervous system. In artificial neural networks, units are neuron-like; connections, axon-like; and the weights of connections function in ways analogous to synapses.

Another attraction is that connectionist networks, with their units sensitive to varying strengths of multiple inputs, carry out in natural ways 'multiple soft constraint satisfaction' tasks - assessing the extent to which a number of non-mandatory, weighted constraints are satisfied. Tasks of this sort occur in motor-control, early vision, memory, and in categorization and pattern recognition. Moreover, typical networks can re-programme themselves by adjusting the weights of the connections among their units, thereby engaging in a kind of 'learning'; and they can do so even on the basis of the sorts of noisy and/or incomplete data people typically encounter.

The potential role of connectionist architectures in the computational theory of cognition is, however, an open question. One possibility is that cognitive architecture is a 'mixed architecture', with classical and connectionist modules. But the most widely discussed view is that cognitive architecture is thoroughly connectionist. The leading challenge to this view is that an adequate cognitive theory must explain high-level cognitive phenomena such as the systematicity of thought (someone who can think 'The dog chases the cat' can also think 'The cat chases the dog'), its productivity (our ability to think a potential infinity of thoughts) and its inferential coherence (people can infer 'p' from 'p and q'). It has been argued that a connectionist architecture could explain such phenomena only if it implements a classical, language-like symbolic architecture. Whether this is so, however, and, indeed, even whether there are *such phenomena to be explained, are currently subjects of intense debate.*

1 What is a connectionist network?

Units and their activation. A unit in a connectionist network can be an input unit, an output unit or a 'hidden' unit. Input units can directly receive signals from sources external to the network; output units can directly send signals outside the network. Input and output units are sometimes called 'visible' units because of their direct interaction with external factors. The 'hidden' units of a network are those units (if any) that send or receive signals from outside the network only by means of sending or receiving signals from other units, as in the following 'Hamming net':



Simple connectionist network (from Dinsmore 1992: 9)

A network can have one or more layers of hidden units, or no hidden units at all.

At any time, a unit is in an activation state. The kinds of activation states units occupy can vary from one network architecture to another, from being merely active or inactive, to being in discrete states of three or more levels of activation, or to having continuous degrees of activation, either bounded or unbounded. The activation state of a unit is indexed by a real number, typically on the interval [0,1], called the 'activation value' of the state.

Each unit computes an output function that maps its current state of activation to an output signal. The signal is not an encoded message such as a data structure, but a degree of activation indexed by a real number. While an output function can be linear, typically it is some threshold function. If a unit has a negative bias, it may send 0 (or the null signal) unless its activation value exceeds a certain threshold; if it has a positive bias, the unit may send a

certain output value unless its activation value falls below a specific threshold. Networks in which units compute non-linear output functions exceed in computational power networks in which units compute only linear ones.

Patterns of connectivity. The activation state of a unit U_i causally influences the degree of activation of a unit U_j by means of the activation output U_i sends to U_j. The direction of such causal influence is the direction of activation spread or flow. There is a connection from a unit U_i to a unit U_j when, but only when, the output of U_i can exert an influence on the activation state of U_j via a direct path within the network - one along which there is no intermediate unit. Connections are thus the direct causal routes along which units send signals to their output units. In some networks, two units can mutually influence each other, and thus a unit can be related to another both as input and output. In 'auto-associative' networks, each unit is connected to every other unit, including itself; in other networks, there are various restrictions on which units are connected.

When units can mutually influence each other, information processing is interactive. In 'recurrent' networks, there are connection patterns that contain loops. That is, a unit is either related to itself as an input unit or there is a series of unit connections from the unit back to itself; thus, the output of a unit at one time can causally influence its activation state at another via activation flow. In 'feed-forward' networks, information processing is non-interactive: activation flows in a single direction from input units to output units via whatever layers, if any, of hidden units the network contains. The Hamming net, for instance, is a feed-forward network with three layers of units, one of which is a layer of hidden units (see diagram above).

The causal influence a sending unit exerts on a receiving unit depends on two intrinsic properties of their connection: its weight (or strength); and whether it acts to increase (excite) or decrease (inhibit) the level of activation of the receiving unit. The notation 'w_{ij}' is used to stand for a real number which indexes the connection from unit U_i to unit U_j by its weight and kind; the number is positive/negative when the connection is excitatory/inhibitory, respectively. The weight of the connection is the absolute value of w_{ij}.

In many networks, the extent and kind of causal influence a unit U_i exerts on a unit U_j is indexed by the product of w_{ij} and the activation value of U_i. The total network activity input to U_j is the sum of all such causal influences: it is the sum of the product of each input activation value and the real number indexing the weight and kind of connection it bears to U_j. (If there are inputs from sources external to the network, they must likewise be indexed by real numbers and included in the summing.) But in some networks, the net input function to a unit - called the 'propagation rule' - is more complex. In 'competitive' networks, units form pools: the units in a pool are all mutually inhibitory - that is, they bear inhibitory connections to each other - while units outside the pool are excitatory to one or more units in the pool. And still more complex patterns of connectivity are possible.

Units respond to the signals they receive either by changing their level of activation or by remaining at the same level. Which response occurs is a function of three factors: the total activity input to the unit, the unit's current activation state, and the unit's bias (if any). The activation function for a unit maps the unit's net input (a sum or weighted sum) and current activation state to an activation state of the unit. In Hopfield networks, units have a sigmoidal (S-shaped) response to net input: their activation levels only increase by a given amount given an increase in net input; after that, they level off and increase no further. But units can also have Gaussian (bell-shaped) activation functions and other sorts of non-linear ones as well.

Local and global effects. Units process information by computing an activation function and an output function. By means of such local interactions among units, global consequences ensue. The behaviour of a network as a whole is a consequence of the pattern of connectivity exhibited by its units at a time and the global activation state of the network at that time. The latter is indexed by a vector (ordered list) of real numbers, the activation value of each unit in the network at that time being indexed by one and only one element of the vector.

Network information processing is characterized as the evolution through time of global patterns of activation. The set of all possible global activation states of a network is its activation space, whose dimensionality is exactly equal to the number of units in the network. The vectors that index possible global states of the network pick out points in the activation space, and the temporal evolution of the network is characterized as a trajectory through that space.

2 Computation, representation and learning

A network itself can behave in a rule-like way to compute functions from one vector to another. The argument of the function is a vector indexing a pattern of activation over input units, and the value of the function for that argument is a vector indexing a pattern of activation over output units. In response to any input activation pattern representing an argument of a particular function, a network with a specific pattern of connectivity can be disposed to produce the output activation pattern representing the value of the function for that argument. The network computes the function when this disposition is activated.

Representations within a network can be of one of two kinds: local or distributed. A representation is *local* if it is (or is realized by) an *individual* unit in a certain activation state. A representation is *distributed* if it is (or is realized by) a pattern of activation over a *group* of two or more units. A network computes functions from one sort of representation to another by computing the corresponding vector-to-vector function in the manner described in the preceding paragraph.

The pattern of connectivity exhibited by the units in a network functions like an 'implicit' look-up table program. A look-up table program looks up (unique) answers to questions posed to it. Patterns of activation over input units function like questions posed to the network (for example, 'To what category does this belong?'), and patterns of activation over output units function like answers to the questions ('To category C.'). Unlike typical classical look-up mechanisms, networks do not *explicitly* store the answers as data structures; rather, the answers are, so to speak, *implicitly* contained in the pattern of connectivity. The patterns of activation over output units can be construed as data structures. But such patterns are produced in response to the network's inputs as a result of the network's pattern of connectivity, rather than retrieved from some storage location in the network. A network's memory, it is said, is in its pattern of connectivity.

A network's pattern of connectivity is not architecturally fixed, for the weights of connections are not. Connectionist networks can programme themselves, via weight change, to execute a given look-up table program. Thus, the look-up table need not be pre-programmed into the network; the network can develop it in response to training. It is taught to recognize a pattern, for instance, by being trained on examples of the pattern: presented with examples of the target pattern as inputs, its outputs are assessed by some evaluation procedure and the weights of connections are then adjusted (see the discussion of learning rules below); the network passes through a number of cycles of this procedure until it acquires the disposition to respond to each input in the right way (or to some desired degree of accuracy). Networks can be trained to associate patterns and to extract features from data sets in response to statistical regularities in them.

During training, weight change occurs in accordance with learning rules. One of the earliest is *Hebb's rule*: when two units are activated at the same time, the strength of the connection between them will be increased (see Hebb 1949). By conforming to this rule a network can learn associations that depend on correlations between activations of units in the network. The generalized *delta rule*, typically called 'back-propagation', is currently the most widely used learning rule in connectionist research. For a given input activation pattern, the actual output pattern is compared with a target output pattern. The difference between the two is then propagated back into whatever connections were used to get the actual output. If the match is good, then the connections among units which contributed to the output are strengthened; if the match is poor, then the relevant connections are reduced in strength. Back-propagation is worthy of special note because it dispelled concerns about the possible computational limitations of network architectures raised by Minsky and Papert's critique of perceptrons - simple two-layered networks (Minsky and Papert 1969).

Back-propagation is a kind of supervised learning rule since it results in weight changes based on an externally generated report on the network's performance - an error signal. Networks can engage in unsupervised learning by monitoring their performance by means of internal feedback via direct or indirect loops.

3 Networks and multiple soft constraint satisfaction

Many kinds of networks are capable of finding optimal (or near-optimal) solutions to problems whose solution involves assessing multiple soft constraint satisfaction - problems Minsky and Papert (1969) called 'best-match' problems. There has been considerable success in analysing a wide range of cognitive problems as such problems. Content-addressable memory - recalling something or someone on the basis of a partial characterization (for example, 'a game played on a court with a ball that players try to drop through a hoop') - is analysed as a

pattern-completion task involving multiple soft constraint satisfaction. And categorization using conceptual schemata has been analysed similarly. This seems to many to capture Wittgenstein's 'family resemblance' account of concepts, whereby objects satisfy a concept by virtue of sharing any of a variety of resemblances, as well as Rosch's related account of concepts in terms of the resemblance of an object to a 'prototype' (see Concepts §7). And recently Prince and Smolensky's optimality theory (1993) outlines how parsers using multiple soft constraint satisfaction might serve for the parsing of natural language.

The basic network approach to such problems is due to Hinton (1977). Each unit represents a hypothesis (note that such representations are local and unstructured), and each connection puts constraints among hypotheses. If, for example, hypothesis H is evidence for hypothesis H', there is a positive connection from the unit representing H to the unit representing H'; and the connection is negative if H is evidence against H'. The tighter the confirming or disconfirming evidential relation, the greater the strength of the connection. If one hypothesis implies another, the connection from the first to the second will be such that the output unit must be on if the input unit is on; if two hypotheses are incompatible, they may be mutually connected in such a way that they cannot both be on. Since input units can also receive external input, the corresponding hypotheses can receive direct confirming or disconfirming evidence from the environment. The fact that different hypotheses may have different a priori probabilities is handled by biasing the relevant units. The overall goodness of fit of a particular hypothesis to the evidence is measured by the sum of the individual constraints on the activation value of the unit representing the hypothesis. The activation values of units range between a minimum and a maximum. The maximum value means that the hypothesis should be accepted, the minimum that it should be rejected, and intermediate values correspond to intermediate states of certainty. The constraint satisfaction problem is thus reduced to one of maximizing this overall goodness of constraint fit.

Implementing such a procedure by a network has proved fruitful in many areas of cognitive science. For example, one of the basic problems in computational vision is to characterize the computational procedure by which the visual system arrives at representations of the scene before the subject's eyes from the subject's retinal images (see Vision). A leading research programme characterizes the computational procedure as a Bayesian decision procedure implemented by a network (see Probability, interpretations of).

One problem that arises for procedures for solving best-match problems is avoiding local maxima of goodness of fit. The Boltzmann machine, developed by J. Hinton and Terence Sejnowski, employs the standard method for avoiding them. Exploiting a computational analogue of the metallurgical process of annealing - whereby metals are heated to a little below their melting point and then cooled very slowly so that all their atoms have time to settle into a single orientation - random noise (heat) is introduced into network activity. The noise functions to jar the network out of local landscape valleys (which correspond to low goodness peaks) so it can explore other parts of the energy landscape to find the global energy minimum (the highest goodness peak). When the network reaches a stable state, it has settled or relaxed into a solution. Given sufficient time, the Boltzmann machine can solve any computational problem for which weights exist.

4 Connectionism and artificial intelligence

Work in connectionist computation has had perhaps its greatest impact in the field of artificial intelligence (AI), which attempts to develop intelligent machines (see Artificial intelligence). AI research into connectionist networks has yielded fruit in many areas of business and industry. (The connectionist machines are, however, virtually always simulated on standard commercial computers, rather than actually manufactured.)

Networks are especially proficient at solving so-called connected problems - ones that do not divide into independently solvable subproblems. Consider, for example, 'the travelling salesman' problem: a salesman must visit each of a number of cities, beginning and ending his journey at the same city, and visiting all the others only once. The problem is to find the shortest route he can take. (If there are, for instance, twenty cities, then there are over 6.5 billion combinations of routes.) Since which city the salesman visits depends on which cities he has already visited, the problem does not divide into independently solvable subproblems. Such problems are decidable, and can thus be solved by classical methods. However, as the connected parameters of the problem increase, there is an exponential increase in the computational resources required to solve them by classical means. Connectionist networks are able to solve such problems much more efficiently. Hopfield's network is able to find a nearly optimal solution to the travelling salesman problem in a small number of training cycles.

Networks are also proficient at pattern-recognition tasks and at learning to perform such tasks. One network that has received a great deal of attention in the popular press is Sejnowski and Rosenberg's NETtalk (1987), which learns to associate letters with phonemes. The network drives a synthesizer that produces pronunciations of the phonemes. After sufficient network training, the synthesizer sounds like a robotic voice literally reading English texts presented to it.

There have been some comparative studies between networks employing back-propagation and classical learning systems employing various members of the family of 'top-down inductive decision trees' (TDIDT), which are kinds of 'production systems' (Quinlan 1987). The studies compared decision trees and networks with respect to speed and predictive accuracy of learning categorization tasks, both from accurate data and from noisy and/or incomplete data (for example, Fisher and McKusick 1989; Mooney *et al.* 1989; Shavlik *et al.* 1991). One data set used in a comparative study is Sejnowski's and Rosenberg's 'NETtalk Full' (Shavlik *et al.* 1991). The TDIDT member that figured in the study was ID3. There was no statistically significant difference in the predictive accuracy of the network using back-propagation and ID3. ID3 was 64.8% accurate; the network was 63.0% accurate. Moreover, both ID3 and back-propagation degraded at roughly the same rate as features were removed from the data set, but ID3 was five times faster than back-propagation. On the NETtalk-A data set, ID3 was 63.1% accurate and the network was 66.4% accurate; and ID3 was 100 times faster. (In studies for some data sets, TDIDTs are as much as 1,000 times faster than networks using back-propagation; but that is unsurprising since back-propagation is notoriously slow.) Speed aside, other such comparative studies indicate that networks using back-propagation are roughly equivalent to various TDIDT members in terms of predictive accuracy and graceful degradation in the face of noisy and/or incomplete data.

New learning algorithms for networks are being explored, as are new TDIDT algorithms. Moreover, in the field of machine learning, there is currently much research into machines that integrate networks and TDIDTs into a single machine architecture. This research proceeds without regard to either neural or psychological plausibility; its aim is not to model how cognizers actually learn, but rather to build better learning machines.

5 Connectionism and neuroscience

The nervous system appears to be a system of neural networks. We are, however, largely ignorant of its workings. By and large, it is unknown what functions any type of neuron computes, and how information generally is encoded in the brain. But enough is known to know that, while connectionist networks were inspired by neural networks, extant connectionist networks are not neurally realistic: no type of connectionist network yet proposed is instantiated by any actual neural network. On the basis of anatomical and immunocytochemical criteria of type individuation, it is estimated that the number of types of cortical neurons is somewhere between fifty and 500 (Sereno 1988). Different types of neurons appear to perform specialized functions. These functions are not well understood, but there is no evidence that any type computes activation functions or output functions computed by units in any extant network model. Further, there is no neural analogue of back-propagation. And while parts of dendrites appear to be able to act as independent information-processing units, this has no analogue in extant connectionist networks (Churchland and Sejnowski 1992).

None the less, work in computational neuroscience with the members of a certain family of connectionist networks, namely artificial neural networks, is playing an important role in increasing our knowledge of the nervous system. Computational neuroscience strives for more and more realistic networks with the aim of someday modelling actual neural-network information-processing (Churchland and Sejnowski 1992). Important pioneer work has already been done. For example, there has been considerable development of artificial neural network models of low-level vision phenomena such as stereopsis (binocular vision) and colour constancy, and of motor-control phenomena such as the vestibular-ocular reflex (that enables eyes to focus on a fixed point as the head moves). Indeed, artificial neural network theory is presently the only approach to understanding information processing in neural networks.

6 Connectionism and the philosophy of psychology

The bulk of the philosophical literature on connectionism has focused on one of two issues: first, the prospects of cognitive architecture proving to be thoroughly connectionist; and, second, the consequences for folk psychology should it prove to be so.

There is nothing approaching a consensus regarding the second issue. Some philosophers argue that connectionism could vindicate folk psychology (for example, Horgan and Tienson 1995); others, that it would entail the elimination of many folk-psychological notions, for example, belief (Ramsey *et al.* 1990). One obstacle to adjudicating such disputes is that it is unclear how wrong folk psychology must be for eliminativism to follow; another is that it is controversial exactly what folk psychology entails (Stich and Warfield 1995). For example, it has been claimed that folk psychology is committed to the view that having beliefs requires having sentence-like mental representations. It is true that according to the *classical computational* theory of belief, a belief that *P* consists in a disposition to compute in certain ways with a mental sentence that means that *P*. However, this account of belief is a scientific hypothesis, not something implied by folk psychology. Similarly, it has been claimed that folk psychology is committed to the view that when an agent acts, some, but not all, of the agent's beliefs and desires play a causal role in producing the action. However, this too is an open question: some philosophers view folk psychology as an interpretive device, rather than as a system of causal hypotheses (see Folk psychology; Eliminativism).

Perhaps the most serious obstacle to adjudicating these disputes is that there is nothing approaching a consensus about what connectionist *cognitive* architecture would be like. For example, some connectionists maintain that a connectionist cognitive architecture would contain sentence-like representations as a phenomenon emerging from the network (Smolensky *et al.* 1992). Indeed, there is no consensus about what kinds of network activity would count as realizing mental activity or what sorts of network states would count as realizing beliefs, desires, intentions or the like. While there has been much interesting connectionist work in cognitive modelling, a connectionist alternative to the classical conception of cognition as rule-governed symbol manipulation has yet to be articulated. The value of discussions of whether folk psychology would be vindicated is that they bring this issue of an alternative conception into bold relief (see Cognitive architecture; Language of thought).

7 Crux of the classical/connectionist debate

Discussions of the prospects of cognitive architecture proving to be thoroughly connectionist have taken place in the context of discussions of whether a connectionist theory of cognition could replace the classical theory.

It is universally acknowledged that cognitive architecture is not a Turing machine architecture (in which a scanner reads and prints symbols on an infinitely long tape - see Turing machines), nor a von Neumann architecture (in which a central processor controls what occurs in different addresses - see Neumann, J. von). The classical theory of cognition is not committed to either of these classical architectures. Neither is it committed to any extant classical programming languages such as LISP (or 'list processor'), nor to rules being explicitly represented, to processing being sequential ('serial' as opposed to 'parallel'), to data structures being explicitly stored in memory locations, nor to there being an executive overseer. Classicism is committed only to our cognitive architecture including (1) a symbol system with a compositional syntax (a 'language of thought') and (2) types of algorithmic and heuristic causal processes in which complex symbols participate in virtue of their logico-syntactic structure (see Language of thought; Mind, computational theories of). The crux of the classicism/connectionist architecture debate is whether an adequate cognitive architecture could fail to include both (1) and (2).

According to proponents of replacement connectionism, connectionism can yield an adequate, alternative theory of cognitive architecture to the classical theory. Jerry Fodor and Zenon Pylyshyn (1988) have raised the most widely discussed challenge to this position. They point out that classicism can explain systematic relationships among capacities to have thoughts involving the exercise of the same concepts in the same intentional mode (for example, belief, desire, intention and so on): for example, that someone able to think that the dog is chasing the cat would normally be able to think that the cat is chasing the dog, and that someone able to want the cat to be on the mat would normally be able to want the mat to be on the cat. They point out, further, that classicism can explain the 'productivity' of thought - that is, the fact that people can have a potential infinitude of thoughts; and that it can explain the inferential coherence of thought processes, for example, the truth-preserving relations between premises and conclusions in a valid argument. They challenge replacement connectionists to show how a connectionist architecture could explain such phenomena without implementing a classical one.

One response to the challenge is to concede that it cannot be met, and to embrace the implementational option, or propose some mixed architecture. Another is to reject the challenge on the grounds that there are no such cognitive

phenomena to be explained. A third is to attempt to meet the challenge: to show how connectionism could explain such phenomena without implementing a classical architecture. While each response has defenders, discussion has focused mainly on the third. It is generally acknowledged that networks with only local representations are inadequate to explain the cognitive phenomena in question. However, some connectionists (most notably Smolensky 1991, 1995) argue that it is possible for a network architecture with distributed representations to yield explanations of systematicity, productivity and inferential coherence without implementing a classical architecture. Whether this is so is a subject of intense debate (see, for example, Fodor and McLaughlin 1990; McLaughlin 1993a, 1993b, 1997). The potential role of connectionism in the computational theory of cognition remains unresolved.

Conscience

To have a conscience involves being conscious of the moral quality of what one has done, or intends to do. There are several elements under the idea of conscience. First, conscience can signify those very moral convictions persons cleave to most firmly and judge themselves by. Second, the notion may cover the faculty by which we come to know moral truths (assuming there to be such) and apply them to ourselves. Third, conscience can be said to concern the examination by a person of the morality of their desires, actions and so on. Finally, conscience can involve guilt: one can suffer from a 'bad conscience'. In the Christian tradition, conscience can be viewed as 'the voice of God within' each of us. Several of these aspects of conscience are expressed in Milton's lines from Paradise Lost, when God says: 'And I will place within them as a guide/My umpire Conscience' (III: 194-5).

There are many elements comprehended under the idea of conscience, and it is sensible to consider these separately since they do not always occur together. First, someone's conscience may be considered to comprise those fundamental moral convictions by keeping to which they retain a sense of their moral integrity and decency as people. In this sense something is 'a matter of conscience', or raises 'questions of conscience', if it touches on such central personal principles. According to this signification, different people can have markedly different consciences, but, it would be argued, we should still respect each person's conscience since to force them to violate the demands of their conscience is to force them to give up their sense of their own integrity. This line of argument may be resisted, however. We are told that some Nazis saw carrying out the extermination programme as a matter of conscience. To force them not to do this does not seem to involve a moral problem. In reply, it can be said that only consciences which are 'enlightened' require respect. The question whether conscience can be enlightened, or fallible and perverted, leads on to a second strand in thinking about conscience.

According to this strand, a person's conscience comprises their capacity to come to acquire moral standards for their own conduct; or, more specifically, their capacity to come to know moral truths (see Moral knowledge §1). This sense, strictly more basic than *conscientia* itself, is referred to as *synderesis* or *synteresis* by Aquinas (*Summa theologiae*), by which he means the power to grasp fundamental moral principles, a power supposedly common to all persons and one which, if functioning appropriately, results in our all knowing the same basic principles. However these very basic principles (such as 'Do good' and 'Eschew evil') are too general to help us know how to act in particular circumstances. We require also a capacity to derive more concrete principles which will give us moral guidance, and a capacity to apply these appropriately to our own circumstances. These two secondary functions are the province of conscience strictly understood, according to Aquinas. Errors in conscience can arise in deriving these more specific rules of conduct or in their application even if *synderesis* is held to be infallible. Questions can arise, analogous to those referred to earlier, about whether it is better to follow one's conscience even though it may prove to be fallible or to violate one's conscience which, if it is erroneous, may then mean one ends up doing the right thing. Talk of a 'perverted' conscience may mean that a person's ultimate convictions are judged to be perverse, as in the first strand identified; or that their capacity to know good from evil, in general or in the particular case, has been distorted or corrupted.

Building on the above, we may note a third emphasis in the idea of conscience, to do with the care, intensity and frequency with which someone examines the moral credentials of their desires, feelings, actions and omissions. Someone may have an 'overworked' or 'oversensitive' conscience, by making too much a matter of moral self-scrutiny or by being too scrupulous about any and every moral doubt which may arise (if one can be overscrupulous about such things). On the other hand, a person's conscience may be 'fast asleep' and need 'awakening' or 'quickening', as in the famous painting by Holman Hunt, 'The Awakening Conscience' (1852). They do not lack a conscience, but rather the will or disposition to use it. Joseph Butler (1726), in a sensitive and important discussion of the moral significance of conscience, emphasized that conscience sometimes 'without being consulted, without being advised with, magisterially exerts itself' (Sermon II) (see Butler, J. §§2-4). I take this to mean that sometimes without, or against, our will or deliberate intention we find ourselves judging our own intentions and deeds critically and in condemnation. This thought leads on to the last aspect of conscience to be considered.

A person may first become aware that they have done something they feel to be wrong or wicked through

experiencing feelings of uneasiness, guilt, or a vague sense of oppression. It may take some thought to discover what deed these feelings attach to, but they can be regarded as central manifestations of having a ‘bad conscience’ about it. Feelings of remorse, shame, dismay, torment and guilt, all forms of self-punishment following from self-condemnation, are major elements in the functioning of conscience. A clear, easy or happy conscience does not usually bring self-congratulatory feelings with it (that would be more like self-righteousness), merely the absence of the pains of a troubled conscience. Popular morality likes to believe that no-one can escape from the toils of a guilty conscience in the end if they commit some terrible deed, however hard they try.

The self-punitive strand in conscience has particularly attracted the attention of psychoanalysts including Freud (1930). Some people can be crippled in their capacity for active life by the savagery and relentlessness of self-punitive guilt incident to, say, feeling aggressive or sexual impulses. Freud held that children ‘internalize’ powerful parental figures as part of their development and, in doing so, can subject themselves to very severe judgments felt to be emanating from these figures. The ‘super-ego’ thus conceived can confront and harangue the child’s ego, and inhibit its expression (see Freud, S. §8; Psychoanalysis, post-Freudian §2). To gain relief from such savage self-censure is not, of course, to become amoral or conscienceless; it is simply to adopt a less punitive attitude to moral endeavour.

It has been argued that moral regulation via the medium of an inner witness, self-judgment and self-punishment, is not so central to all cultures as it has been to our own. Some anthropologists contrast ‘guilt’ cultures with ‘shame’ cultures; in the latter it is fear of public exposure and loss of ‘face’ which is the principal vehicle of moral regulation (see Moral sentiments §3).

It is inappropriate to ask which of the above four aspects of conscience comprises its essence or makes up what it ‘really’ is. In different contexts one or more of these aspects may be in view and it is more important to appreciate the variety of elements here than it is to determine which of them is definitive of conscience.

Consciousness

Philosophers have used the term 'consciousness' for four main topics: knowledge in general, intentionality, introspection (and the knowledge it specifically generates) and phenomenal experience. This entry discusses the last two uses. Something within one's mind is 'introspectively conscious' just in case one introspects it (or is poised to do so). Introspection is often thought to deliver one's primary knowledge of one's mental life. An experience or other mental entity is 'phenomenally conscious' just in case there is 'something it is like' for one to have it. The clearest examples are: perceptual experiences, such as tastings and seeings; bodily-sensational experiences, such as those of pains, tickles and itches; imaginative experiences, such as those of one's own actions or perceptions; and streams of thought, as in the experience of thinking 'in words' or 'in images'. Introspection and phenomenality seem independent, or dissociable, although this is controversial.

Phenomenally conscious experiences have been argued to be nonphysical, or at least inexplicable in the manner of other physical entities. Several such arguments allege that phenomenal experience is 'subjective'; that understanding some experiences requires undergoing them (or their components). The claim is that any objective physical science would leave an 'explanatory gap', failing to describe what it is like to have a particular experience and failing to explain why there are phenomenal experiences at all. From this, some philosophers infer 'dualism' rather than 'physicalism' about consciousness, concluding that some facts about consciousness are not wholly constituted by physical facts. This dualist conclusion threatens claims that phenomenal consciousness has causal power, and that it is knowable in others and in oneself.

In reaction, surprisingly much can be said in favour of 'eliminativism' about phenomenal consciousness; the denial of any realm of phenomenal objects and properties of experience. Most (but not all) philosophers deny that there are phenomenal objects - mental images with colour and shape, pain-objects that throb or burn, inner speech with pitch and rhythm, and so on. Instead, experiences may simply seem to involve such objects. The central disagreement concerns whether these experiences have phenomenal properties - 'qualia'; particular aspects of what experiences are like for their bearers. Some philosophers deny that there are phenomenal properties - especially if these are thought to be intrinsic, completely and immediately introspectible, ineffable, subjective or otherwise potentially difficult to explain on physicalist theories. More commonly, philosophers acknowledge qualia of experiences, either articulating less bold conceptions of qualia, or defending dualism about boldly conceived qualia.

Introspective consciousness has seemed less puzzling than phenomenal consciousness. Most thinkers agree that introspection is far from complete about the mind and far from infallible. Perhaps the most familiar account of introspection is that, in addition to 'outwardly perceiving' non-mental entities in one's environment and body, one 'inwardly perceives' one's mental entities, as when one seems to see visual images with one's 'mind's eye'. This view faces several serious objections. Rival views of introspective consciousness fall into three categories, according to whether they treat introspective access (1) as epistemically looser or less direct than inner perception, (2) as tighter or more direct, or (3) as fundamentally non-epistemic or nonrepresentational. Theories in category (1) explain introspection as always retrospective, or as typically based on self-directed theoretical inferences. Rivals from category (2) maintain that an introspectively conscious mental state reflexively represents itself, or treat introspection as involving no mechanism of access at all. Category (3) theories treat a mental state as introspectively conscious if it is distinctively available for linguistic or rational processing, even if it is not itself perceived or otherwise thought about.

1 Pre-Cartesian uses of 'consciousness'

As elsewhere in philosophy, Descartes' writings mark a major shift in philosophical preoccupation with consciousness (see Descartes, R.). Pre-Cartesian philosophers of mind rarely emphasize the terms 'conscious' or 'consciousness' (or clear equivalents). Post-Cartesian philosophers of mind rarely avoid such emphasis. This section compares Descartes' usage with earlier usage.

Descartes typically speaks of being 'conscious' to refer to an allegedly *intimate* source of knowledge about *one's own mental occurrences*. In the 'Conversation with Burman' he says that 'to be conscious is both to think and to reflect on one's thought' (1648: 335), where the term 'thought' extends widely, as in the 'Second Replies', to

'everything that is within us in such a way that we are immediately conscious of it' including 'all the operations of the will, the intellect, the imagination and the senses' (1641: 113). Descartes seems to treat everything mental as introspectively conscious, in these passages and elsewhere (see the 'Fourth Replies', 1641: 171). Elsewhere, however, Descartes seems to deny that introspection is complete, as in the *Discourse on Method*: 'many people do not know what they believe, since believing something and knowing that one believes it are different acts of thinking, and the one often occurs without the other' (1637: 122).

The resulting focus on the scope and limits of introspective knowledge (see §§6-7) is apparently responsible for the modern uses of 'conscious' and 'non-conscious' to mark a potential distinction between two kinds of mental states. Introspected states are (introspectively) conscious, while others, if any, are (introspectively) unconscious. Pre-Cartesian authors do not use the word 'conscious' to mark such a distinction, although some may be committed to the distinction, either implicitly or in other terms (Whyte 1962). To take a rather spectacular example, Socrates claims in Plato's *Meno* that since one's soul 'has been born many times' and 'has learned everything that there is', 'seeking and learning are in fact nothing but recollection' (81c-d). This seems to require that one has latent knowledge of which one can at best become aware with great difficulty (see Plato §11).

Many pre-Cartesian writers share commitment to a special fountain of reflective knowledge, often called 'inner sense'. In *Summa theologiae* Aquinas posits a 'common sense' which enables one, for example, to 'tell white from sweet', and adds that this common sense 'is also able to sense sensation itself, as when somebody sees that he is seeing' (I.78.4). This responds to Aristotle's apparent claim, in *On the Soul*, that it is 'by sight that one perceives that one sees' rather than by another sense (III 2, 425b12). On these views, the subject matter of such inner awareness is more restricted than for Descartes, including sensation but perhaps not other mental processes. It may even be that, for Aristotle, the relevant 'inner' perception - by which one sees that one sees - is directed at one's external sense organs *themselves* and not at anything Descartes would consider strictly 'mental'.

A nearer equivalent to 'introspective consciousness' is the Sanskrit term '*manas*', used widely in Hindu texts for a 'mind-organ' that functions like the external sense organs. For instance, the *Vaiśeṣika Sūtra* (*c.* 3rd century BC) claims that 'Intellect, pleasure, pain, desire, aversion, effort are perceptible by the internal organ' (Radhakrishnan and Moore 1957: 411). This inner perception is carefully distinguished from 'inferential knowledge', and is framed so as not to involve introspection of a 'self'. Indeed, while Descartes holds that he can introspect himself as a 'thinking thing', Hinduism characteristically claims that introspection reveals no 'true self' distinct from one's mental states, and Buddhism characteristically denies that there are 'thinking things' at all (see Momentariness, Buddhist doctrine of; Self, Indian theories of).

The word 'conscious' derives from the Latin words '*cum*' ('together with') and '*scire*' ('knowing'). In the original sense, two people who know something together are said to be conscious of it 'to one another', with the irresistible connotation that they are privy to a scandalous secret. By extension, one can be conscious 'to oneself' of secret shames - whence the original use of 'consciousness' for conscience, the inner accuser silently sharing knowledge of one's transgressions. This archaic moral sense of 'consciousness' is not a concern in this entry (see Conscience).

The Latin conjunction of '*cum*' and '*scire*' also has a use in which the prefix is merely emphatic, so that being 'conscious of' something simply means knowing it, or knowing it well. In this sense the word 'conscious' can also be used as an adjective: a 'knowing' being such as a normal person is a conscious being, while an 'unknowing' being such as a plant or sleeping person is an unconscious being. 'Conscious', like 'knowing', can be used in this way for things *with* minds but not for things with*in* minds, such as mental states. People and animals know things - are conscious of things - but mental states do not themselves know things. Thus, for example, Aquinas uses 'conscious' to describe *bearers* of mental states - such as human beings, animals and God - but not to describe mental states - not even 'seen' seeings. Since the main philosophical problems about consciousness concern the more modern distinction between conscious and unconscious *states*, this entry focuses neither on the distinction between conscious and unconscious *subjects*, nor on the broad 'knowing' sense of 'conscious' (see Knowledge, concept of). In effect, Descartes refashions the 'knowing well' sense of 'conscious', regimenting it for a *particular* source of knowing, introspection. Issues about the specific epistemological status of introspection are a central concern of this entry.

2 Post-Cartesian uses of 'consciousness'

Descartes' use of 'consciousness' for reflective knowledge spread rapidly through the next generation of European philosophers. In *An Essay concerning Human Understanding* Locke writes, as he does of 'reflection', that 'Consciousness is the perception of what passes in a Man's own mind' (1689: II.i.19); Leibniz's term for this is 'apperception'. In his *Critique of Pure Reason* Kant goes on to distinguish between 'empirical apperception' of a 'flux of inner appearances' - mentioning that 'Such consciousness is usually named *inner sense*' - and 'transcendental apperception' which is alleged to be a 'pure original unchangeable consciousness' that reveals a 'fixed and abiding self' (A107; see Kant, I. §6). This entry discusses one's introspective access to the 'flux' of particular events within one's mind, rather than substantive introspective knowledge about one's self - about whether one is made of physical or spiritual components, and whether one persists through time (see Mind, bundle theory of; Introspection, epistemology of §4; Personal identity).

In the broader 'knowing' sense (see §1), a creature is conscious of something just in case it knows something, independently of whether this knowing is itself introspectible. This ancient sense of 'conscious' lingers on, and broadens to cover any kind of belief or cognition (whether or not it is 'knowledge'), and any kind of attitude about something (whether or not it is 'cognitive'). In this sense, a creature has consciousness if it has any kind of 'intentional' mental state. By extension, the state itself can be said to be a state of consciousness, even if it is not introspectible. (This is distinct from the widespread claim that all conscious states are intentional - that 'all consciousness…is consciousness of something' (Sartre 1943: 11). On this broad sense of 'conscious', by definition, all 'ofness' is conscious ofness.) As twentieth-century philosophers of mind and language most often pursue concerns about intentionality using terms other than 'consciousness', intentionality will not be explored in this entry (see Intentionality).

In a still broader sense, 'mind' and 'consciousness' are synonyms, as are 'being mindful of' something and 'being conscious of' it, so that any kind of mental state (whether or not it is an 'attitude') is a state of consciousness. When Hegel (§5), Marx or Lukács speak of 'unhappy', 'false' or 'class' consciousness, or when political activists attempt to 'raise' consciousness, their concerns are usually equally well rendered using a general term such as 'knowledge', 'thinking', 'attitudes' or 'mentality' in place of 'consciousness'. It is not clear that their concern is with introspection, since they refer mainly to thoughts about (or seemingly about) non-mental things, independently of whether these thoughts are themselves introspectively conscious. (When Hegel refers to thoughts explicitly about the mind, he uses 'self-consciousness' rather than 'consciousness'.) Likewise, many scientific writings officially on 'consciousness' are about mentation and mentation-like activity in general, avoiding any question of whether the activity is introspectively conscious. Since these broad uses of 'consciousness' seem to introduce no distinctive philosophical perplexities, this entry puts them aside.

With the dawn of scientific psychology in the late nineteenth century, the central philosophical controversies about consciousness centre around whether consciousness can ever be explained by an objective science of the mind. The biologist Thomas Huxley provides an early attempt to express the sense of mystery: 'How it is that anything so remarkable as a state of consciousness comes about as a result of irritating nervous tissue, is just as unaccountable as the appearance of Djin when Aladdin rubbed his lamp' (1866: 210). Since that time there have been many scientific advances in understanding the mechanisms of perception, thought and communication, and many philosophical advances in understanding the nature of intentionality and meaning. According to Thomas Nagel and many other philosophers, such advances must leave an unexplained residue, concerning *what it is like* to have phenomenally conscious experiences (as illustrated in the introduction; see Nagel, T. §4). Nagel writes that 'Consciousness is what makes the mind-body problem really intractable', identifying 'subjectivity' as its most troublesome feature:

> Fundamentally an organism has conscious mental states if and only if there is something it is like to *be* that organism - something it is like *for* the organism. We may call this the subjective character of experience…every subjective phenomenon is essentially connected with a single point of view, and it seems inevitable that an objective, physical theory will abandon that point of view.
>
> (1974: 166-7)

Until quite recently, the agenda for the philosophy of mind has been set more by epistemology than by the sciences of mind. Consequently, introspective consciousness has been the most central and important philosophical notion of consciousness. The remainder of the entry is divided between the explanation of phenomenal consciousness and

the epistemology of introspective consciousness.

3 Subjectivity and the phenomenal

Nagel argues that physical theories cannot explain one's phenomenal consciousness, because they abandon one's point of view (see §2). Science does indeed abandon one's point of view, in so far as one need not be able to understand or defend the theory (if one lacks relevant concepts or evidence), and in so far as subjects with other points of view should be able to understand and defend the theory. But does abandoning a point of view prevent *describing* the point of view, or the features viewed from that point? Even if Nagel is correct that one's point of view and one's phenomenal experience are 'essentially' connected, they may not be *exclusively* connected. An objective physical theory of phenomenal consciousness would presumably allow that phenomenal features are accessible from multiple points of view - for instance, both by some form of introspection and by some form of neurophysiological or psychological observation and theory. Furthermore, if experiences are *necessarily* introspectible or introspected (see §6) this might explain Nagel's claim that phenomenal features are 'essentially connected with a single point of view'.

Frank Jackson (1982) amplifies Nagel's challenge in his 'knowledge argument' against 'physicalism', the thesis that the world is wholly physical. He imagines a super-scientist, Mary, who has never seen anything coloured because she lives her life in a black-and-white room. From a black-and-white television in this room, she learns *all* the objectively specifiable physical (and causal or 'functional') facts in the world. When she finally leaves the room and first sees colour, Jackson argues, she learns a *new* fact about the nature of phenomenal experience; she might exclaim, 'Oh! It is like *this* to see red!' The new fact Mary learns cannot be identical to a physical or functional fact, or else it would be among the facts Mary already knows before leaving the room. So no wholly physicalist account of phenomenal facts can be true (see Colour and qualia; Qualia).

Most responses to Jackson's argument involve denying that Mary learns a new fact upon experiencing red. On some views, she learns *how* to do new things - to imagine experiencing redness or to recognize redness visually - without coming to know *that* any new fact obtains. On others, she learns that an *old* physical fact about experience obtains, but comes to know it *in a new way* - via introspective access or via new concepts. For example, one proposal (Lycan 1990) compares the relevant introspective ways of representing one's experiences with *simple inner-perceptual demonstratives*, ways of knowing colour experience that would be unavailable to Mary from within the black-and-white room. Consider an analogy: when one perceives a banana and thinks of it demonstratively - as 'this' - those who do not perceive the banana cannot think of it in the same way - simply as 'this' (while staring at something else). Likewise, if one's introspections of one's experiences involve some demonstratives of them, this would explain why these representations cannot strictly be shared by someone who does not 'perceive' the same experiences but merely thinks *about* them. (For marks against this strategy, see Raffman 1995; for further elaboration, see Tye 1995: 173-8.)

Even among philosophers who accept that phenomenal consciousness is *some* physical or functional process, there are doubts about the possibility of explaining it. Colin McGinn (1991) suggests that human beings are forever blocked from knowing the 'link' between the brain and consciousness, roughly because introspective consciousness gives no knowledge of brains, while neuroscientific access to brains gives no access to consciousness. Critics respond that one might learn the explanatory link by theoretical inference from *joint* introspective and scientific data, such as correlations between phenomenal features and brain states (see Flanagan 1992: ch. 6).

In slightly different ways, Jackson, Joseph Levine (1993) and David Chalmers (1996) argue that even if one can know what this 'link' *in fact* is, explanations based upon it cannot be as satisfying as other scientific explanations. In essence, the argument is that for any objective, scientific account of phenomenal consciousness, one can *conceive* of a creature that meets the conditions in the account but *lacks* phenomenal consciousness. In the extreme case, it is said, one can conceive of a world that is an exact *physical* duplicate of the actual world - complete with duplicate stars, planets, rocks, plants, animals and philosophers - but which lacks any phenomenal consciousness. All the human-like beings in that world would be non-phenomenal 'zombies'. So the prescientific concept of phenomenal consciousness is not such that scientific premises could necessitate, a priori, conclusions about the phenomenal. In Levine's terms, there is an 'explanatory gap' between physical reality and phenomenal consciousness. By contrast, for example, it is claimed that the prescientific concept of 'water' is such that scientific

premises about H_2O, can necessitate, a priori, conclusions about water. In particular, it is held to be part of our *concept* of water that *if* there is anything roughly unique in the lakes and rivers around us that has a preponderance of features such as boiling, eroding rocks, quenching thirst and so on, then it is water. If science establishes that H_2O meets this condition, then there is no further conceptual possibility that H_2O is not water.

At least three lines of response may be advanced against the explanatory gap argument. One concedes that no scientific premises a priori necessitate conclusions about the phenomenal, but insists that the same is true for scientific explanations of water, and so on. Perhaps someone who believes in water but denies that it boils, is in lakes and so on is making a *false* and *bizarre* claim but are not strictly *contradicting* themselves. The fate of this response presumably depends on the fate of general reservations about a priori or conceptual necessity (see Essentialism; A priori).

The second strategy also concedes the lack of a priori necessity, but attributes it to the idiosyncratic ways in which phenomenal facts are represented - for example, by introspection-based demonstratives (see Tye 1995: 178-81; Demonstratives and indexicals). By comparison, suppose that agent *A* holds banana *B* in front of his face, and comes to accept the demonstrative '*This* is a banana'. This conclusion cannot strictly be deduced from any demonstrative-free *descriptions* of the banana - that *B* is a banana in *A*'s hand, that *A* sees *B*, and so on. The subject could believe all of these premises, and still *conceive* that this is not a banana - perhaps by conceiving that he is not in fact agent *A*. This response to the explanatory gap seems at best to apply only to particular phenomenal conclusions, of the form: it is like *this* to have a given experience. It is an *incomplete* response, since there are phenomenal conclusions without demonstratives, namely, those of the form: there is *something* it is like to have a given experience.

The third strategy is to deny that there is an unbridgeable conceptual gap; in effect, to deny that zombies (non-phenomenal physical duplicates of phenomenal creatures) are even *conceptually* possible. In Nagel-like fashion, Robert Kirk analyses the concept of phenomenality as follows: a creature's phenomenal states are those with different 'characters' that are 'for the creature as a whole' (1994: ch. 5). He explains this in terms of neural states with different 'patterns of activation' that are 'directly available' to 'have different effects on processes of assessment, decision-making, and action initiation'. It follows that if a creature has states with characters for the creature, any physical duplicate of the creature does also. The problem is that Kirk's 'having character' does not express the same concept as Nagel's 'being like something'. Perhaps Kirk demonstrates how states can be 'for a creature', but he does not demonstrate that they are 'like something' for the creature, that is, phenomenal, in Nagel's full-blown sense. For example, *beliefs* may also be realized in different patterns of activation with the relevant direct availability, and so in that sense beliefs may be 'for' a creature, but beliefs are not clearly *themselves* 'like something' for a creature (see §6). Further analysis of the 'like something' idiom would be needed to complete this line of response to the explanatory gap (see Belief).

4 Dualism and the phenomenal

The attraction of subjectivity-based arguments against physicalism makes it important to understand the potential ramifications of various non-physicalist alternatives. The central metaphysical issues concern 'mental causation' and 'emergence' (see Mental causation). The two central epistemological ramifications concern knowledge of other minds and knowledge of one's own mind (see Other Minds).

Physical science promises an explanation of physical events wholly in terms of other physical events. For example, unsupported objects fall, not because they *want* to fall, but because of gravitational forces. Similarly, a large group of neurons cause another neuron to fire, not because of its embarrassment due to peer pressure or its fear of a mob, but because of electrochemical forces. In this way, there should be a purely physical explanation of the activities of brains in producing (reflex or non-reflex) behaviour. Yet *phenomenal consciousness* also seems to have physical consequences on behaviour. When one feels an itch, one scratches; this seems to be in large part *because* of what it is like to itch. But how can an itchy *feel* make a difference, if there is a purely physical explanation of one's hand motions? The physicalist may make room for phenomenal causation by maintaining that the feel of an itch is *wholly constituted by* (or, perhaps, identical with) features of the brain and body (see Mind, identity theory of). The *feel* causes the hand motion, because it is *made of* things that do so, just as the *brain* causes the hand motion by being composed of things that do so (that is, neurons). But this strategy is unavailable to the non-physicalist

who thinks there are mental objects, properties or states that are not wholly composed of physical entities (see Dualism). One possibility for the dualist is to maintain that some physical events are *inexplicable* purely in physical terms - this is Descartes' own position about non-reflex behaviour. Another prominent strategy is to defend 'epiphenomenalism' about the phenomenal, or the idea that, contrary to appearances, phenomenal features are irrelevant to the generation of physical events (see Jackson 1982; Chalmers 1996: ch. 4; Epiphenominalism).

If phenomenal states and features are not wholly constituted by physical states and features, how *are* they constituted? One idea, prevalent among neuroscientists, is that the phenomenal 'emerges' from physical *interactions*. By analogy, water has properties that are not explicable by the properties of hydrogen and oxygen separately. Water dissolves salt, but neither hydrogen nor oxygen does so separately (nor does hydrogen dissolve *part* of salt and oxygen the rest). Analogously, the whole of a phenomenal experience is taken to be more than the sum of its physical parts (that is, the physical entities that help realize it). The initial plausibility of such analogies seems to depend on a too-narrow conception of the 'parts' of a complex entity. A water molecule does have hydrogen and oxygen atoms as parts, but it also has various *relations* among these atoms as other 'parts'. The physical relation of *bonding*, for instance, is as necessary for water as the atoms are. If *all* of the parts of water are counted, it is not clear that water has properties inexplicable by the properties of these parts. This kind of 'emergence' conclusion - one that forgets to 'sum' some of the parts of a whole - is compatible with a wholly physicalist account of water, and of consciousness. In the absence of better analogies, non-physicalist philosophers have more commonly denied that there is *genuine* emergence, emergence of new features that are *inexplicable* in terms of combinations of other features. This leads some non-physicalists to the startling 'panpsychist' claim that mental 'ingredients' of phenomenal consciousness must be present in the tiniest bits of matter capable of comprising brains, and to the claim that phenomenal consciousness is a *fundamental* part of nature - perhaps along with subatomic mass and charge (see Chalmers 1996: 8; Panpsychism).

Epiphenomenalism and panpsychism exacerbate the epistemological problem of other minds, but in opposite directions. It seems that we have excellent, even if not quite *perfect*, justification for believing that other people have experiences. Plausibly, talk of experiences is not simply disguised talk of others' observable behaviour, but is instead to be *inferred* from behaviour with some degree of theoretical risk. Perhaps the inference is in part grounded on drawing an analogy between oneself and others, but inference from a *single* case gives one at best meagre justification for conclusions about others. The residual problem of other minds, then, is to explain how one attains an appropriate level of justification. The physicalist can maintain that one is justified in part because the phenomenal features of experience help explain behaviour - in fact, help cause it. But the epiphenomenalist seems forced to deny this, potentially rendering it *too hard* to attain knowledge of other minds. The panpsychist, on the other hand, renders it *too easy* to attain such knowledge; not only other people but other animals, plants, rocks and protons have mental features.

A final danger with the idea that phenomenal consciousness depends on nonphysical features is that it threatens self-knowledge about one's phenomenal states. The nonphysicalist who believes that zombies are possible believes that two people could be alike in all non-phenomenal respects, while one has phenomenal experience and the other does not. Each could be fully convinced of their own rich, detailed phenomenal experience, but one would be wrong. It is difficult to see how either could justify their belief that they are *not* a zombie, if zombies are possible. Chalmers tries to address this problem by stipulating that non-zombies are *necessarily* distinctively justified:

> To have an experience is automatically to stand in some sort of intimate epistemic relation to the experience - a relation that we might call 'acquaintance.' There is not even a conceptual possibility that a subject could have a red experience like this one without having *any* epistemic contact with it: to have the experience is to be related to it in this way…. [This] is to stand in a relationship to it more primitive than belief: it provides *evidence* for our beliefs, but it does not in itself constitute belief.
>
> (1996: 196-7)

This conclusion anticipates the idea that inner perceptions of one's experiences - taken to be more 'primitive' than reflective beliefs about one's experiences - are necessary for phenomenal consciousness (see §6). But where the non-zombie has inner perceptual states, by hypothesis the zombie has them also. Perhaps what zombies have are *misperceptions*, but this need not lessen their *justification* in accepting these misperceptions at face value, and in believing they have experiences.

Also, the heavy reliance on introspections of experience opens up two alternatives for physicalism. The first is to deny that there is experience at all, but only the favoured kind of introspections *as of* experience. The second - perhaps the more attractive - is to maintain that the favoured kind of introspections are *sufficient* for experience. This is to invert Chalmers' claim that 'to have the experience is to be related to it in this [inner perceptual] way'; if so, this is precisely because to be related to a state in this inner perceptual way is to have an experience. Neither strategy carries obvious commitment to anything nonphysical. (For related objections to 'absent qualia', see Shoemaker (1984: chaps 9, 14); and for a response, see Block (1980). Rey (1986) extends the point, arguing that *non*-psychological requirements on phenomenal consciousness - perhaps biological or neurophysiological ones - would also jeopardize introspective knowledge of experience; see also Chalmers (1996: 7).)

5 Eliminativism and the phenomenal

In addition to subjectivity-based arguments, phenomenally conscious experiences provide other interesting arguments against physicalism. In certain experiences one seems to be aware of phenomenal denizens of an inner mental world: coloured and shaped mental 'images', bodily 'sensations' such as 'pains' that may be throbbing or in one's limb, and inner 'speech' with 'private' volume and pitch. Such alleged mental objects as afterimages, pains and inner speeches, that are naturally reported as having properties of non-mental objects (for example, roundness, throbbingness or loudness), may be called 'phenomenal objects'. The argument against physicalism based on reports of phenomenal objects is simple. In such experiences nothing in one's brain or body or (causally relevant) environment is literally purple and round, literally throbbing and in a limb, or literally soft and medium-pitched. So if phenomenal objects do exist with these properties, they are not among the things in one's brain or body or environment. One must be either a dualist (see §4) or an 'eliminativist' about mental entities with these properties; that is, the physicalist must deny that objects with such properties exist (see Eliminativism).

The challenge for the eliminativist about phenomenal objects is to explain why people are often *tempted* to claims of phenomenal objects, with ordinary perceptible properties. Broadly, the temptation may be attributed to an *ambiguity* or *looseness* in ordinary reports of experiences, or to an *illusion* built into the experiences themselves, which may then be reported strictly and faithfully. Following a suggestion due to Ned Block, Michael Tye (1995) pursues the former strategy by pointing out that people often describe representations as *having* properties that they merely *represent*: the phrase 'a warm thermostat setting' may be used for a thermostat setting *of* warmth, and 'a nude painting' may be used for a painting *of* nudity. It should be no surprise then that people describe experiences *of* colour and shape as themselves *being* coloured and shaped, and so no surprise that, speaking freely, they treat them as images. The other strategy is latent in J.J.C. Smart's suggestion that 'There is, in a sense, no such thing as an after-image…though there is such a thing as the experience of having an image' (1959: 151). On one straightforward construal of 'the experience of having an image', an experience itself *represents* that there is an image with certain features, although there is no such thing (compare with Sartre's 'illusion of immanence', 1940: 5). The illusory-experience view has an advantage over the reporting-based view to the extent that afterimages *look* purple and round, pains *feel* dull or in motion, and inner speech seems to *sound* faint or high-pitched. By contrast, a warm thermostat setting need not itself feel warm, and a nude painting need not itself look nude (any more than other paintings look *clothed*). However, without an account of why experiences misrepresent phenomenal objects, the illusory-experience view does not adequately discharge the eliminativist's explanatory burden (for one account, see Rey 1997).

In addition to phenomenal objects, eliminativists have targeted alleged 'phenomenal properties' of experiences, or 'qualia'. There is not merely 'something' it is like to have a phenomenally conscious experience, but some *particular* 'thing' or things it is like. People sometimes *try* to describe these particular properties, for example, by saying that a given pain is 'sharp' or 'throbbing' to some degree, or that a given visual image is 'blurry' or 'moving'. Even if the eliminativist about phenomenal objects is correct that there are only experiences *as of* sharp throbbing pains and *as of* blurry moving images, descriptions such as 'sharp' and 'blurry' seem in some indirect or nonliteral way to convey particular aspects of what it is like to have these experiences. In a relatively cautious use of the word 'qualia', particular what-it-is-like properties, whatever their nature turns out to be, are qualia.

There are bolder uses of 'qualia' on which the word can apply only to properties of experience that pose challenges to scientific explanation. Some require qualia to be infallibly and completely accessible to introspection, which is puzzling on any plausible scientific explanation of introspection (see §§7-8). Some require

qualia to be inaccessible without introspection - for instance by purely behavioural or neurophysiological tests that one may perform on other people, without relying on an introspective understanding of one's own experience; this seems to preclude explanation of qualia as physical properties discoverable in multiple objective ways (see §3). Perhaps the most controversial philosophical idea about qualia, however, is that they are 'intrinsic' properties of experience. Metaphysicians dispute the correct account of intrinsicality, but the following may serve to convey the intuitive idea, as it applies to experience: for an experience to have a property intrinsically, the experience must have the property solely in virtue of the *spatiotemporal parts* of what realizes the experience. (This is meant to exclude everything that even in part exists when or where the experience does not, for example, stimuli that cause the experience, and behaviour and other mental states that the experience causes.) This seems to preclude explaining qualia in 'functionalist' terms by appeal to the causal role of experiences, or in 'intentionalist' terms by appeal to the representational content of experiences (see Functionalism). Defenders of the intrinsicality of qualia often argue for the possibility of 'inverted qualia', cases in which two experiences differ in qualia even though they have identical causal or representational relations to their mental and non-mental surroundings (see Block 1990).

Qualia in such bold senses have been rejected most forcefully by Dennett (§3). He describes several examples in which changes in whether we like or dislike certain tastes seem to change the tastes themselves, concluding that when someone 'thinks of "that taste" he thinks equivocally or vaguely' and 'need not try - or be able - to settle whether he is including any or all of his reactions' (1988: 61-3). Nevertheless he accepts that, through the changes in likes and dislikes, 'the taste is (sort of) the same', and defenders of intrinsicality may hope to explain such taste similarities by appeal to reaction-independent components of experiences (see Lormand 1994 for further defence of bold qualia).

An argument against the existence of intrinsic qualia can be built upon what G.E. Moore calls the 'diaphanousness' of perceptual experience:

> The moment we try to fix our attention upon consciousness and to see *what*, distinctively, it is, it seems to vanish: it seems as if we had before us a mere emptiness. When we try to introspect the sensation of blue, all we can see is the blue: the other element is as if it were diaphanous.
>
> (1903: 450)

Gilbert Harman argues as follows:

> When you see a tree, you do not experience any features as intrinsic features of your experience. Look at a tree and try to turn your attention to intrinsic features of your visual experience. I predict that you will find that the only features there to turn your attention to will be features of the presented tree, including relational features of the tree 'from here'.
>
> (1990: 39)

Defenders of intrinsicality may claim not to satisfy Harman's prediction. This response gains plausibility in cases of degraded perception (for example, blurred or double vision), and it is not clear how Harman's argument is supposed to generalize from perceptual experiences to bodily-sensational, imaginative or thought experiences (see bodily sensations; Imagery). (For discussion of imagery by a philosopher in sympathy with Harman, see Tye (1995).) The prediction may hold for non-degraded perceptual experiences and perhaps 'upgraded' imaginings such as dreams, and in these cases perhaps it shows that no experienced features *seem* intrinsic to experience. One may hold that some experienced features *are* intrinsic to experience, but only by incurring a burden of explaining why these features seem to belong to trees and other non-mental objects. In fact, this burden remains even if qualia are taken to be *relational* features of perceptual experience, since the relevant experienced features are experienced as if they belong *objectively* to trees, and do not seem in experience to depend on the participation of the perceiver. Just as the eliminativist about phenomenal *objects* of experiences would do well to explain the illusory experience of their *presence*, so the *non*-eliminativist about phenomenal *properties* of experience - whether intrinsic or relational - would do well to explain the illusory experience of their *absence* (see Qualia).

6 Introspection and the phenomenal

Here the discussion begins to shift from phenomenality to introspection. To clarify the apparent difference

between phenomenal and introspective consciousness, consider whether a state can be conscious in one but not the other sense. Can there be *nothing* it is like to have a state, even when one is introspectively aware of it? Can there be *something* it is like to have a state, even when one is wholly unaware of it? The *facts* are murky and controversial, but it is important to be clear about the *possibilities*.

The introduction lists four kinds of states that are most clearly phenomenal: perceptual experiences, bodily-sensational experiences, imaginative experiences and streams of thought. There are mental states not explicitly on this list, notably 'propositional attitudes' such as the belief that snow is white (see Propositional attitudes). Usually one's belief that snow is white is latent and unintrospected, though one can raise it to introspective consciousness easily. Normally there seems to be something it is like to have such an introspectively conscious belief (see Belief). However, there is another possibility to explore. What having the belief 'is like' may be completely accounted for by what it is like to have experiences *accompanying* the belief, such as auditory imaginings of asserting the words 'Snow is white' (or 'I believe snow is white', or 'Mon Dieu! La neige! Blanche!'), or visual imaginings of some fictitious white expanse of snow, together with what William James (1890: 287-8) describes as feelings or imaginings of moving eyeballs, eyelids, brow, breath, jaw-muscles and so on as one thinks. Pending evidence of further aspects of what it is like to have the belief, this illustrates how there can be something it is like *when* one has an introspectively conscious state, although the state itself has no phenomenal character (Lormand 1996). Introspective consciousness - at least of the sorts available to beliefs - is unlikely simply to *be* phenomenal consciousness, and is unlikely to be *sufficient* for it.

Might introspection nevertheless be *necessary* for phenomenality? There is a tension between a 'yes' answer and the view that many species of animals can have experiences - that there is something it is like for cats and dogs to feel pain or to see bright lights, for instance. It is implausible that these beings have Cartesian reflective knowledge *that* they feel pain and see. This would require having *concepts* of feeling pain and of seeing, and perhaps a *self*-concept, and all this would seem to involve capacities beyond the reach of most nonhuman animals - for example, the ability to conceive of *others* as feeling pain and seeing, and the ability to *remember* or *envisage* oneself feeling pain and seeing (see Animal language and thought). Notoriously, Descartes himself accepts that nonhuman animals are 'automata' without mental states of any sort. Defenders of a reflective-knowledge requirement may either mimic this strategy, denying that animals have conscious experiences (Carruthers 1992), or else attempt to minimize the conceptual sophistication needed for the reflective knowledge (Rosenthal 1990).

This tension is more commonly taken to be a serious strike against a reflective-knowledge requirement on phenomenality (see, for example, McGinn 1982: 52; Dretske 1995: 18), especially given that a similar tension arises in the case of human infants. Thomas Reid objects against Locke that 'reflection ought to be distinguished from consciousness', since:

> From infancy, till we come to the years of understanding, we are employed solely about external objects. And, although the mind is conscious of its operations, it does not attend to them; its attention is turned solely to the external objects, about which those operations are employed.
>
> ([1785] 1969: 57)

Even for beings with the requisite conceptual capacities, it seems implausible that reflective knowledge must accompany *each* of their experiences. At any given moment one can attend only to a small proportion of the sensory stimuli one encounters. It is also difficult to attend simultaneously to the outside world and to one's experience of it, as Auguste Comte argues (1842: 21): 'The thinking individual cannot cut himself in two - one of the parts reasoning, while the other is looking on' (see Introspection, psychology of). Nevertheless, plausibly, there is something many inattentive perceptions of unattended stimuli are like; experience would be quite impoverished were it not for the contributions of background noises and odours, pressures on one's feet or seat, moisture under one's tongue, peripheral vision and so on. It is possible to maintain that one continually forms reflective *beliefs* about these experiences, but this fits poorly with the difficulty of *remembering* these experiences (after they change, for example).

An introspective requirement on phenomenality can blunt much of the force of these objections by distinguishing inner *perception* from the formation of reflective *beliefs*, and by distinguishing *inattentive* introspection from *attentive* introspection. Just as one might sense a daffodil without having a concept of daffodils, or a tendency to remember the daffodil, so perhaps one can inwardly sense an experience without having a concept of experiences,

or a tendency to remember the experience. Animals and babies might sense even if they cannot form beliefs; likewise, perhaps they can inwardly sense even if they cannot form reflective beliefs (see Belief). Also, according to Locke, just as there can be passive sensation, so reflection need not be done intentionally or with attention (1689: II.i.7). Along these lines, Brentano distinguishes between inner *perception*, which may be automatic and inattentive, and inner *observation*, which is actively guided by purposeful attention (1874: 29). It is true that a creature's most pressing cognitive needs require mental resources to be directed at the *external* world, but if inner perception is normally inattentive, it need not draw resources away from attentive outer perception (see Bodily sensations). It is an open question whether there can be phenomenal experiences without any kind of introspective awareness of them, even of a primitive sort (but see §7 below).

7 Completeness of introspection

Perhaps more thoroughly than Descartes (see §1), Locke identifies the mental with the introspectively conscious, claiming that it is unintelligible 'that any thing *thinks without being conscious of it*, or perceiving, that it does so' because 'thinking consists in being conscious that one thinks' (1689: II.i.19). This completeness claim has been rejected by most subsequent philosophers, with the prominent exception of some in the broadly phenomenological tradition, following Franz Brentano and Edmund Husserl (see §10).

The main evidence for introspectively unconscious mental processes is that they would fill certain theoretical gaps in the scientific explanation of behaviour and introspectible mental activity. This inferential strategy is most prominent in psychoanalytic attempts to explain otherwise bizarre dreams, associations among concepts, apparent slips of the tongue, emotional disorders, neurotic physiological reactions and so on (see Freud, S.; Psychoanalysis, post-Freudian; Unconscious mental states). Although the scientific status of such clinically-based explanations is controversial (see Psychoanalysis, methodological issues in), alternative explanations are elusive; witness Sartre's difficulties in trying to explain self-deception and 'bad faith' without appeal to unconscious mentation (1943).

Furthermore, many replicable psychological experiments lead to parallel conclusions about introspectively unconscious mentation in more mundane settings. In one family of experiments (Lackner and Garrett 1972), subjects are presented with an ambiguous sentence in one ear, and disambiguating words in the other ear, but so quietly as not to be noticed consciously by the subjects - typically the stimulus is reported as a meaningless noise. Nevertheless, the subjects' interpretations of the ambiguous sentence are predictable from the meanings of the disambiguating words. This is evidence that subjects not only identify but *understand* the words, without introspective consciousness of doing so.

Similarly, there is evidence of vision without introspective consciousness of vision in cases of subliminal visual perception (Dixon 1987) and 'blindsight' (Weiskrantz 1988). In these cases subjects act on the basis of information about the visual features of objects, despite denying - sincerely - that they have relevant visual experiences. Blindsight subjects have damage to certain neural pathways connecting portions of the retina to the visual cortex, yet in some sense they have perceptual states sensitive to these stimuli. For example, some ability to discriminate an 'X' from an 'O' is intact. This is evidenced by the preponderance of correct answers they can give to questions about the stimuli. When asked to reach for objects in blindsight regions, also, some subjects reflexively pre-orient their hand and fingers in ways suited to the specific shapes of the objects. What blindsight patients lack most clearly is any ability to *introspect* their perceptual states and abilities: they deny that they are perceiving; they respond to the stimuli only when coaxed to do so; and even then they take themselves merely to be guessing. Nevertheless, their guesses tend to be correct and their behaviour appropriate to the stimuli.

It is not only in unusual cases that there seem to be introspectively unconscious perceptual states. On virtually all detailed theories of normal vision, for example, cells in each retina register the amount of incoming light at various points, and cause further states representing sudden discontinuities of incoming brightness, which cause further representational states and, eventually, introspectively conscious visual experiences (see Vision). These early layers of visual processing seem well beyond the reach of introspection. Although these processes (unlike, say, blood flow in the brain) have many mentation-like features - they are assessable as correct or incorrect in relation to external stimuli; they may increase gradually in stability as evidence for them mounts; they may play a direct role in modulating intentional visuomotor action, and so on - they are at best somewhere in the vague boundary between the mental and the non-mental.

To the extent that introspectively unconscious perceptual states are phenomenal, they present a new threat to the claim that introspection is necessary for phenomenality (see §6). Disagreement arises about whether cases of subliminal perception or blindsight involve phenomenal consciousness - perhaps blindseeing is like something, despite the subject's sincere denials; at any rate the cases are not clear enough to weigh decisively against the necessity claim.

There is more dispute about whether non-introspectible information-bearing states in early visual processing are phenomenally conscious. On the view that they are, it would be difficult to explain why phenomenal visual experiences are not continually like double images, given that one has *separate* left-eye-caused and right-eye-caused early visual states. On behalf of the view, one possibility is that there is something it is like *for one's early visual systems* to have certain states, although there is nothing it is like *for one* to have them. Although this is a possibility, it seems no more likely than the possibility that there is something it is like *for one's neurons* when they fire.

8 Reliability of introspection

Even if introspective consciousness is limited, it may be epistemologically interesting as an especially reliable means of access within its domain (see Introspection, epistemology of). Many philosophers have thought that introspective access to mental facts is more reliable than access to other empirical facts. Augustine writes in *On the Trinity* that 'nothing can be more present to the mind than the mind itself' (X.3.5), and asks rhetorically, 'what is so intimately known as the mind, which perceives that it itself exists and is that by which all other things are perceived?' (VIII.6.9). Descartes devotes his *Second Meditation* to an argument that the mind is 'better known' than the body, and Locke also claims that our knowledge of 'Things without us' is 'not altogether so certain, as our intuitive Knowledge' (1689: IV.xi.3). As with completeness, most subsequent philosophers reject the *infallibility* of introspection, although many would agree that it is *relatively* reliable.

The claim of introspective infallibility is extremely bold. In other empirical domains, at best certain mechanisms keep one's beliefs in rough accord with the facts (for example, mechanisms of perception, reason and memory, and the persistence of facts when one is not continually checking them). But mechanisms fail; a mechanism of this complexity that could never possibly fail would be a miracle 'at least as mysterious as papal infallibility', according to Dennett (1988: 55). The same reason to expect fallibility holds for introspection: if there is the slightest mechanism correlating one's thoughts with one's thoughts about them, it should be breakable, and if there is no mechanism, a perfect correlation between the two would seem to be sheer luck.

Furthermore, scientific investigations of introspection have revealed widespread 'confabulation' in self-access. In identifying one's beliefs and motivations, one systematically but sincerely reports attitudes one thinks rational or statistically normal in the circumstances, even if one does not have them (see Nisbett and Wilson 1977; Introspection, psychology of). For instance, in the 'bystander effect', increasing the number of joint witnesses to a person's need decreases the likelihood that any of them will assist. But bystanders rarely report this as a factor in their decision whether to help, often claiming instead to have reached a decision based solely on their own likelihood of success. According to Nisbett and Wilson, much allegedly 'introspective' access to attitudes consists of self-directed, fallible guesses, based at best on common-sense abilities to rationalize behaviour. Also, since these abilities are at work in one's access to others' mental states, this self-directed guesswork provides some reason to suppose, with Ryle (1949), that introspective consciousness is not interestingly more reliable than access to other minds.

In the face of this evidence, the Cartesian may attempt to identify a restricted domain in which a kind of introspection is comparatively reliable (*Ericsson and Simon 1993*) or even infallible (Lormand 1994). The model of rationalizing or statistical guesswork does not extend easily to introspection of phenomenally conscious experiences. For example, untutored subjects offer consistent and apparently reliable reports of 'feelings' of stinging (rather than throbbing) pain when a limb has restricted blood flow. They seem not to infer these feelings in the way one might form beliefs about another's pain feelings, since no common-sense principles of rationality dictate that one should feel stinging rather than throbbing, and since the subject need know no relevant statistical information about how people feel in these circumstances.

Against any attempt to find a restricted domain safe for infallibility, Dennett argues that one can easily be wrong

about the ‘changes and constancies’ in one’s experience over even brief intervals of time (1988: 59). This weighs against infallible *memory* access to what it was like to have *past* experiences, though not against infallible or especially reliable access to *current* experiences.

9 Introspection as inner perception

How should introspective consciousness be explained? While Lockean inner perception (see §2) has some contemporary defenders, most notably David Armstrong (1980), this view has fallen on hard times in philosophy of mind.

How is inner perception supposed to be distinctively analogous to outer perception? Of course, inner perceptions are not generated by literal inner eyes, ears and their attendant experience-forming processes. Armstrong explains inner perception as being, like outer perception, ‘selective’ (incomplete), ‘fallible’ and ‘causal’. This illuminates little, since probably all cognitive processes have these features, even one’s most theoretical (versus perceptual) scientific beliefs, for example, those about quantum mechanics or cosmology. Another initially tempting idea is the Hindu one (see §1) that inner perception is a causal but *non-inferential* source of evidence about mental states (or, more cautiously, that it is as low as outer perception on flexible, all-things-considered inference). Might a mental state be introspectively conscious only if its bearer inwardly perceives the state, in this sense? One strong objection is that introspective access often involves self-directed theoretical inferences, often confabulatory ones (see §8). It is therefore best to restrict inner-perception views to current phenomenal experience (in accordance with the suggestions at the end of §8).

An influential objection is that inner perception requires phenomenal ‘sense data’ interposed between physical objects and one’s perceptions of them (see Sense-data; Perception). Accepting inner perception may seem to involve accepting that one at best perceives outer objects *indirectly* through perceptions of phenomenal mental entities. But such a mediation theory would have difficulty explaining why inwardly perceiving sense-data did not in turn require perceiving further entities (‘sense-data data’) and so on, infinitely. Such arguments against sense-data have been mounted against inner perception (as in Shoemaker 1994), but with unclear effect. Inner perceptions need not be *interposed* between objects and one’s perceptions of them - the causal chain in perceiving a table need not proceed from the table to an inner perception and then to a perception of the table. Rather, on a more natural view, the causal chain goes directly from the table to a perception of the table, and then (in cases in which the table perception is introspectively conscious) to an inner perception of the perception of the table.

Dennett argues that inner perception of a ‘Cartesian theatre’ of consciousness would be too sharp to explain the vague conscious/unconscious distinction, and that inner perception is wasteful - ‘once a discrimination has been made once [in outer perception], it does not have to be made again’ (1991: 127). Yet it can be vague whether something is inwardly (or outwardly) perceived, and inner perception of an outer perception need not re-represent features the outer perception is *of*, but instead may newly represent features *of* the outer perception (see Lormand 1994, for further defence of inner theatres).

Perhaps the most influential objection to inner-perceptual introspection is based on Moore’s ‘diaphanousness’ claim (see §5). The objection is that, since each outer-perceptual modality (seeing, hearing and so on) makes its own distinctive contribution to what experience is like, an additional modality of inner perception should be expected to make *its* own contribution, to change what it is like. But what it is like to introspect a perceptual experience seems simply borrowed from what it is like to have the experience itself (McGinn 1982: 50-1). When one tries to attend to features of normal experiences, one normally ‘sees through’ the experiences to outer objects. So a fundamental disanalogy between outer perception and alleged inner ‘perception’ is that the former, but not the latter, has its own phenomenology or perceptual quality. This is evidence against inner perception of current phenomenal experiences.

On the other hand, if inner perception is necessary for phenomenality (see §6), then instead of *borrowing* phenomenal qualities from an outer perception, as the diaphanousness objection alleges, inner perception helps *generate* these qualities together with the (otherwise phenomenally unconscious) outer perception. This may explain why inner perception does not add further qualia to an outer-perceptual experience; inner perception may *already* make its phenomenal contribution in the generation of an outer experience with qualia (see Qualia).

10 Alternatives to inner perception

Two rivals to inner-perception accounts treat introspective access as epistemically *less* intimate than inner perception. First, James maintains that introspection is always retrospective (1890: 187-), largely in reaction to Comte's denial that the mind can simultaneously split between ordinary thinking and awareness of that thinking (see §6). James is unhappy with Brentano's response to Comte - that *inattentive perception* can be split between outer and inner domains - because James seeks to defend the reliance on careful, attentive introspective reports in experimental psychology (see James, W. §2). Second, some maintain that introspection is always laden with theoretical (versus perceptual) inferences. The experimental evidence for confabulation and expectation-driven inference (see §8; compare with Lyons 1986) suggests that introspection is *often* theory-laden and retrospective, but does not suggest that *all* cases of introspective consciousness are, including the *seemingly* non-inferential consciousness of phenomenal experiences that *seem* to persist while being accessed.

One theory of consciousness that combines naturally with theory-ladenness is Rosenthal's 'higher-order thought' theory (1990). (A thought or belief is 'higher-order' in virtue of being about mental entities rather than non-mental entities.) According to Rosenthal's view, a mental state is conscious just in case one forms, in a suitably direct way, a thought that one has the state. The state may generate its higher-order thought through inference so long as these inferences are not themselves conscious. This condition is intended to rule out cases in which one comes to think about a state through very indirect inference - say, solely through believing the testimony of a psychologist. On this view, even if introspective access to phenomenally conscious experiences is somehow inferential, it would *seem* non-inferential simply because one lacks higher-order thoughts about the inferences.

At the other extreme from defenders of theory-ladenness and retrospection, many phenomenologists reject inner perception as not being intimate *enough* to explain introspective access. On one suggestion, some introspectively conscious mental states 'reflexively' represent *themselves* (in addition to representing other things). This conclusion is often embraced to avoid an infinite regress threatening the assumption that introspection is complete (see §6): an experience represents itself rather than being represented by a separate introspective state which (assuming completeness) must in turn be represented by a separate introspection of the introspection, and so on. Brentano argues that 'The presentation which accompanies a mental act and refers to it is part of the object on which it is directed' (1874: 128). Husserl also suggests that 'In the case of a perception directed to something immanent [that is, roughly, mental],…perception and perceived form essentially an unmediated unity, that of a single concrete cogitatio' (1913: 112). And Sartre insists that 'the first consciousness of consciousness' - what he calls 'pre-reflective consciousness' - 'is one with the consciousness of which it is [a] consciousness' (1943: 13-14). Given the prevalence of inferential, confabulatory access to one's mental states, reflexivity theories, like inner-perceptual ones, are best restricted to current phenomenally conscious experiences rather than to other mental states. Again, there is a possibility that one's only access even to these experiences is somehow much more confabulatory or inferentially sensitive to expectations than ordinary perception is, but pending evidence for this possibility the restriction to phenomenal experiences is reflexivity's best hope.

Since one often suffers ordinary perceptual illusions, the more analogous introspection is to perception, the more likely it would be that one would suffer naïve introspective illusions about what one's conscious experiences are like. But it rarely if ever happens that one mistakes, say, a dull pain for a sharp pain, in the way that one mistakes a roadside cow for a horse. This may be evidence that introspection is sometimes neither inner perception nor self-directed theoretical inference, but a process with fewer breakable causal links. Some introspective access may be like one's psychologically *primitive* abilities to shift among mental states. Just as the transition from believing *that p and q* to believing *that p* presumably takes place without intermediate inference or inner perception, so might the transition from (say) believing *that p* to believing *that I believe that p*, or the transition from *having a dull pain* to believing *that I have a dull pain*. As Shoemaker proposes:

> Our minds are so constituted, or our brains are so wired, that, for a wide range of mental states, one's being in a certain mental state produces in one, under certain conditions, the belief that one is in that mental state. This is what our introspective access to our own mental states consists in. The 'certain conditions' may include one's considering whether one is in that mental state…. The beliefs thus produced will count as knowledge, not because of the quantity or quality of the evidence on which they are based (for they are based on no evidence), but because of the reliability of the mechanism by which they are produced.

(1994: 268)

A challenge for this view is to explain lawful and systematic *patterns* among introspectible and non-introspectible states, without an *ad hoc* assumption, for each pattern, that it happens to be 'wired' to higher-order beliefs in the right way. For example, why are brain states governing autonomic bodily functions not introspectible? Why are perceptual experiences introspectible but not subliminal perceptions and early perceptual states? Why does it seem easier to introspect one's fleeting thoughts than one's deeply held beliefs?

All of the theories described thus far in this section reject the etymological suggestion that 'introspection' is a kind of inner perception, while retaining the assumption that a subject's introspective 'access' to a mental state is always a matter of somehow *representing* the state. Further alternatives emphasize other forms of access to a state, or the state's functional relations to processes other than a subject's awareness of them. Verbal reportability is the process most frequently appealed to as an alternative requirement for introspective consciousness (Dennett 1978), in keeping with ordinary and scientific reliance on reportability as a symptom of consciousness. One threat is that reportability may only seem relevant to consciousness because it correlates somewhat with inner-directed representation. Normally, in reporting, one *perceives* one's reporting - hears one's speech, feels one's facial motions, and so on - and is thereby in a position to *understand* one's reports - to recognize one's own voice and realize which mental states one's words express. By contrast, if there is speech without any kind of self-perception, perhaps as in some forms of hypnosis or sleeptalking, this may not seem sufficient for, or even relevant to, introspective consciousness.

Dennett's construct is nearer to Block's notion (1995) of 'access consciousness', as distinguished from introspection and from phenomenality. In Block's terms, a mental state is access conscious if it is poised for free rational control of inference and action. The relevant actions may, but need not, include verbal actions, and the relevant inferences may, but need not, include Cartesian reflective knowledge. Although access consciousness has played little role in the history of philosophical discussions of consciousness, many contemporary writers employ comparable notions in attempts to explain consciousness generally (*Dennett 1991*; Tye 1995; Chalmers 1996).

Consent

*A concept of central importance in moral, political and legal philosophy, consent is widely recognized as justifying or legitimating acts, arrangements or expectations. In standard cases, a person's consent to another person's acts removes moral or legal objections to or liability for the performance of those acts. Thus, in medical practice the informed consent of a patient to a procedure can justify the physician's actions. In law, the maxim '*volenti non fit injuria*' (the willing person is not wronged) governs a wide range of acts and transactions, from the economic to the sexual. And in politics, it is often supposed that it is 'the consent of the governed' that justifies or makes permissible both governmental policies and the use of official coercion to compel obedience to law. Consent may be given in a variety of more and less direct forms, but its binding force always rests on the satisfaction of conditions of knowledge, intention, competence, voluntariness and acceptability of content.*

1 Meaning and importance

Consent is an act by which one freely changes the existing structure of rights and obligations, typically by undertaking new obligations and authorizing others to act in ways which would otherwise have been impermissible for them. In standard cases, one consents to an act or arrangement in response to a request by others; but consenting is so strongly linked with such acts as promising, contracting, taking oaths and entrusting, that it is best to regard all of these sources of self-assumed obligations as kinds of consent (as in Locke's political philosophy; see Locke, J. §10). In the most general terms, then, consent is any act by which an agent deliberately and suitably communicates to another the intention to undertake by that act new obligations and to convey by that act new rights to others. Given the satisfaction of various conditions, consent then authorizes, permits, justifies or legitimates actions by others or arrangements on which they may rely.

It is important to distinguish consent thus understood as a positive act from the weaker notions of consent - an attitude of approval, acceptance or agreement or as mere passivity, acquiescence or submission. These weaker forms of consent are far less important than and quite different from consent properly so-called. A 'pro-attitude' is neither necessary nor sufficient for true (morally binding) consent. Cases of grudging, off-hand or insincere consent show that a positive attitude is not necessary, while commonplace cases in which we approve of an arrangement without having in any way altered (or attempted to alter) the existing structure of rights and duties show that such an attitude is not sufficient. Similarly, one may passively submit to or even acquiesce in the control of a bully without thereby incurring new obligations of future compliance. Binding consent must be a positive act with the explicit, conventional, or otherwise clear meaning of a voluntary undertaking.

Justification by appeal to consent is especially important within the philosophical structure of liberal thought. Liberalism conceives of persons as self-conscious sources of value, whose choices of plans and actions are morally important and who have rights to govern themselves (within the bounds set by the rights of others) (see Liberalism). Consent is seen as the means by which this individual moral liberty may be limited in a fashion consistent with respect for liberty. For the consensual undertaking of obligation is one kind of use of personal liberty, a use which makes morally possible new and beneficial forms of social interaction. Justification by consent also has the advantage of being a relatively uncontroversial style of justification, since nearly everyone allows that what one has freely agreed to do ought to be done.

2 Forms and conditions

Attempted justifications by consent have appealed to a wide variety of forms of consent. The most fundamental divisions are those between personal and impersonal consent and between actual and hypothetical consent. Consensual justification of an act or policy with respect to some individual usually involves showing that the individual (expressly or tacitly) personally consented to it; but theorists have also appealed to the consent of the majority of an individual's colleagues (for example, fellow citizens) or to the consent of an individual's ancestors (for example, the founders of the society). Justification by appeal to personal consent is by far the most convincing of these options, since the authority of majorities over us seems to depend on our prior personal consent to be governed by them, and our forebears could not possibly have been authorized to consent for us.

Justification by consent also standardly appeals to the actual consent of the affected persons. This actual consent

may be given either by some discrete act or by some ongoing series of acts (such as active participation in the practices of some group). And actual consent may be either express or tacit (implicit, indirect). Express consent is consent given by an explicit verbal or written undertaking or by other direct but nonverbal consensual acts (such as raising one's hand). Tacit consent is given by actions or omissions (such as inactivity or silence) that do not involve an explicit undertaking, but that none the less constitute the making of a morally significant choice in the context of a clear, noncoercive choice situation. Some attempted justifications, however, appeal not to actual but to hypothetical consent. Hypothetical consent can be ideal (what fully rational persons would consent to), counterfactual (what real persons could or would have consented to, had they been pressed to give their consent) or dispositional (what real persons would have consented to, had they been able). Only appeals to the last of these (by which we justify, for example, imposing medical treatment on an unconscious injured person) seem to be genuine justifications by consent. Appeals to the others are really attempts to justify by showing that an arrangement is best or acceptable, independent of people's consent.

Consent of whatever form can only justify acts or arrangements given the satisfaction of a complex set of conditions for binding consent. These conditions can be divided into five categories. First, there are knowledge conditions. Where one is deceived or misled about an arrangement, or where one is otherwise non-negligently ignorant of crucial facts, apparent consensual acts may not bind (because consent is not 'informed'). Second, binding consent must be intentional, not only in the sense that the acts themselves must be intentionally performed, but also that they must involve the intention to give consent and thereby alter existing moral relations. Third, consent can only be given by the competent, which may exclude in various contexts apparent consent given by the insane, severely retarded, emotionally disturbed, immature, intoxicated and so on. Fourth, binding consent must be voluntary, limiting it to cases not involving the extraction of consent by coercion, undue influence, exploitation, unfair bargaining advantage and so on. Finally, consent only binds given acceptability of content. In most legal systems, for instance, agreements you make to commit crimes, become a slave or allow yourself to be killed are not enforceable. The moral basis for such rules could be either the alleged inalienability of the rights at issue or the contradiction supposedly involved in the creation of moral obligations to do the immoral.

3 Philosophical applications

Discussions of consent are most common in three areas of philosophical debate. In medical ethics the idea of informed consent is basic (see Medical ethics). Agreements to undergo some surgical procedure, for instance, are binding (and limit the physician's liability) only if patients understand (as far as they are able) basic facts about the nature of the procedure, its risks, costs and alternatives. In legal philosophy, much discussion of the proper structure of contract law turns on analyses of consent. And what constitutes consent is central to the definition of crimes like rape and sexual assault, where a showing of free consent to an act by a competent adult generally defeats criminal charges.

But by far the most numerous philosophical treatments of consent occur in political philosophy, where theorists argue the merits of consent theories of political obligation and authority (see Obligation, political; Authority). According to consent theory, the obligations of citizens to obey the law and support their governments and the authority or rights their governments have over them derive only from consent. The sort of consent relevant to this political justification is variously claimed to be actual and personal (Locke 1690; Beran 1987; Simmons 1993), impersonal or hypothetical (Rawls 1971; Pitkin 1965-6), discrete or ongoing (Walzer 1970; Pateman 1979). Since express consent is relatively rare in political life, it is commonly argued that consent can be given tacitly by continued residence in a state one is free to leave (Locke 1690), by voting (or possessing the right to vote) in democratic elections (Plamenatz 1968; Weale 1978) or by full and direct participation in political life (Pateman 1979). Many also argue, however, both that the conditions of knowledge, intention and voluntariness rule out many of those alleged sources of political consent and that taking seriously the ideal of government by consent forces the acknowledgement that no existing governments are in fact legitimate under these terms (Simmons 1993; Green 1988; Pateman 1979).

Consequence, conceptions of

The idea of one proposition's following from others - of their implying it - is central to argument. It is, however, an idea that comes with a history attached to it, and those who blithely appeal to an 'intuitive' or 'pre-theoretic' idea of consequence are likely to have got hold of just one strand in a string of diverse theories. This entry introduces the main alternatives - to call them rivals would be too strong, since it suggests that they are necessarily in competition with one another. Simply put, consequence may be conceived as a relation that is or is not modal in character, and is or is not formal. Thus for Aristotle, consequence is both necessary and formal; for Chrysippus it is necessary but not formal; for Bolzano and Tarski it is formal but not necessary; and for Philo and Russell it is neither necessary nor formal. Conceptions of consequence that are neither necessary nor formal are also needed if justice is to be done to deduction in science, the law and daily life. Cutting across all these other differences there is a perennial controversy about relevance. Does implication always require a full-blooded connection between premises and conclusion, or may it hold simply because of some property of either separately, for example, because the premises are impossible?

1 Aristotle

Alone among the persons discussed here, Aristotle never defined his conception of consequence. A definition can be supplied, however, that brings out its distinctive features: necessity, formality and relevance. Namely, a number of premises imply a conclusion if, for all premises $P, \ldots$ and conclusions *Q* of the same logical form as the given ones, if $P, \ldots$ are (or were) true, then necessarily *Q* is (would be) true.

The ingredient of necessity here (unlike formality) features in Aristotle's definition of a syllogism. It is required by his demand that proofs should produce 'understanding' (*epistēmē*), coupled with his claim that understanding something involves seeing that it cannot be otherwise. Hence, a proof needs to establish the necessity as well as the truth of its conclusion, which means not only starting from necessarily true axioms but proceeding by steps that preserve necessity as well as truth.

A part of Aristotle's project of axiomatizing science was to separate out those lines of argument that are applicable to all the sciences because they depend purely on topic-neutral terms such as 'every', 'some' and 'not'. These arguments are 'logical' in the special sense in which Aristotle sometimes - not always approvingly - uses the word to signify 'abstract'. The distinction between logical - that is, topic-neutral - and extralogical terms is not clear cut, but he sidesteps the difficulties by selecting a fixed handful of logical terms for study at any one time. Logicians have done the same ever since, splitting consequence in predicate logic, modal logic and so on, rather than lumping them into one broad relation of logical consequence.

Since an extralogical term does no work in making a logical argument valid, the argument remains valid if the term is replaced by any other. In other words, as the definition emphasizes, logical consequence is 'formal'. This feature is exploited by Aristotle's innovation of inference schemes, in which letters take the place of the non-working terms. The combination of formality and an artful selection of working terms creates opportunities for systematization and a mathematical treatment of the subject.

The definition uses counterfactuals because that seems to give the best fit with Aristotle's position on relevance. Where *P* is impossible and *Q* unconnected with it, 'If *P* were true *Q* would be true' is quite impossible to assess, and such cases are duly excluded by his dictum that premises only imply conclusions involving the same terms. But if a scheme is valid whenever its instances can be assessed (as with the syllogistic moods), he assumes that it holds universally; that is, even when the premises are impossible.

2 Chrysippus, Philo and Diodorus

Our knowledge of the fourth century BC dialecticians Chrysippus, Philo and Diodorus is fragmentary and second-hand, but they appear to have made two lasting contributions to the subject of consequence, one distinctly unhelpful, the other of enormous importance (see Philo the Dialectician §2; Diodorus Cronus §3).

Expressions of the form ' follows from ' or ' implies ' need to be completed by sentences embedded in quotation marks or 'that' clauses. As any logic teacher knows, this is not something that comes naturally, and the simpler 'If

P, *Q*' form is a convenient shorthand. The Greek dialecticians seem to have turned it into a regular convention, making the conditional *the* vehicle for discussing consequence. Apart from the other drawbacks of the convention, its blurring of an object language-metalanguage distinction is liable to make a study of consequence look like a contribution to propositional logic. This is especially unfortunate, since their great contribution was to propose the first definitions of consequence and inaugurate a debate about it.

For Chrysippus (the attribution is not certain but strongly probable), premises imply a conclusion if their truth is incompatible with its falsity. 'A man is running' thus implies 'An animal is moving'. As a class, such analytic implications are logical in a broad sense but not in Aristotle's special one; they are necessary without being formal.

For Philo of Megara, an implication holds if - for whatever reason - it is not the case that the premises are true and the conclusion false.

Diodorus Cronus' definition is that 'it neither was nor is possible' that the premises be true and the conclusion false. But since he equates the possible with what is or will be true, this amounts to saying that an implication holds if and only if Philo's condition is satisfied at every time.

Little has survived of the debate itself, alas, but relevance was certainly one issue, for we know that where *P* is impossible, 'If *P*, not-*P*' was acceptable to Diodorus but not Chrysippus. Another issue is likely to have been the extreme weakness of Philo's definition, to which Diodorus' looks like a critical rejoinder. To defend (and perhaps motivate) Philo's definition, one need only ask why there should be a higher standard for the steps of an argument than for its starting point. Premises do not have to be necessarily true, so why should conclusions have to follow *necessarily*? Weak as it is, Philo's definition captures what *Principia Mathematica* (1910-13) calls the 'essential property' of implication; that what is implied by a true proposition is true. It still seems far-fetched to suggest that, for example, all true propositions imply one another, but Philo has been defended even on this point. Russell (1919) distinguishes the presence of an implication from its practical utility for inference. To infer any truths from any others would indeed be *valid* (his word, his italics), but if they are already known to be true there will be no need to infer them, so that inference will in fact only take place if Philo's condition is known to obtain independently, a much stricter requirement.

3 Medieval logic

Medieval logicians tended to follow the ancient dialecticians' expository convention. Thus their 'sequences' (*consequentiae*) tend to be conditional propositions, though their discussion is appropriate to consequence: a sequence is typically said to be 'sound' (*bona*; *valet*) rather than true. The conditional convention lingered into modern times, as witnessed in the ambiguous status of Gentzen's '*Sequenzen*' and Russell's 'material implication'.

As this suggests, medieval logicians were familiar with all the ancient conceptions of consequence. They classified them into 'formal', that is, Aristotelian, and 'material'. Material consequence was subdivided into '*simpliciter*' (absolute), that is, Chrysippian; and '*ut nunc*' (as things are), that is, Philonian, the maxim '*ex falso sequitur quodlibet*' (from a falsehood anything follows) being a reminder of the latter. A few writers created a further subdivision, '*per accidens*' (incidental), to cover a Diodorean conception.

One medieval contribution has left a lasting mark on the subject. We have seen that different ancient conceptions produced different answers about relevance. The medieval development of propositional logic appeared to settle the question by producing a proof that *any* conclusion *Q* really does follow from an impossible premise *P*. The proof runs from *P* to P or Q, and thence, together with the necessary truth not-*P*, to *Q*. Ironically, the credit for this is generally given not to, say, William of Soissons, but to C.I. Lewis, a logician and historian of logic who had no time for the Middle Ages. The topic is still controversial: Bolzano argued that nothing at all follows from an impossibility, and not all modern logicians accept the Lewis proof (see Relevance logic and entailment §1). However, most follow the medieval line, which, when used to reform Chrysippian consequence, produces the familiar textbook formula for validity: 'It is impossible for the premises to be true and the conclusion false'.

4 Bolzano

We saw that Aristotelian consequence is formal, but this does not depend on its being specifically logical: a

comparable relation based on *any* division between working and non-working terms will automatically be formal with respect to the latter. Bolzano exploits this insight in the context of a theory of propositions that are - unlike the propositions mentioned elsewhere in this entry - non-linguistic items, composed of ‘ideas’ (1837). A conclusion is said to follow from a number of premises with respect to an arbitrary choice of ideas if every substitution for those ideas that turns the premises into true propositions also turns the conclusion into a true one. The other logical notions are relativized in a similar way. Bolzano is happy to include ‘logical consequence’ as a special case, that is, consequence when every extralogical idea is treated as substitutable. But his heart is in proving theorems about relative consequence in general. (Since he also broke with the old conditional expository convention, his results are unambiguously intelligible to the modern reader.)

Bolzano’s definition is non-modal. Indeed, a modal relation seems to be ruled out by his theory of ideas. His emphasis on the immutability of ideas and propositions and their reference to the actual, suggests that he cannot allow, as Frege can, that a false proposition *P* could be true in different circumstances. In different circumstances *P* itself would stay false; what would be true would, by hypothesis, be a different proposition. (Moreover, his resolutely non-linguistic stance prevents him from identifying it.) It follows that a modal definition of consequence on the lines of ‘Whatever the circumstances might be, if *P* were true *Q* would be true’ will not work (and cannot be rescued by appealing to ‘the proposition corresponding to *P*’).

5 Tarski

A century after Bolzano, Tarski took a similar approach to logical consequence, but where Bolzano had worked with non-linguistic propositions, he dealt in sentences. Given this choice, the obvious first step would be to replace Bolzano’s substitutions of ideas by substitutions of words. This would produce the following definition (labelled (F) by Tarski, 1936):

(F) A conclusion follows logically from a number of premises if every substitution for the extralogical vocabulary that makes the premises true, makes the conclusion true.

Indeed, Quine takes just this line when he defines a logical truth as a sentence that remains true under every substitution for its extralogical vocabulary. But the problem with such definitions is that in a particular language there may not be enough words of the right kind, so that an inference may come out as logically valid, or a sentence as logically true, simply because the counter-instances happen to be inexpressible. Quine plays down the difficulty by claiming that it will not arise if the language is ‘reasonably rich’, that is, capable of expressing arithmetic. His claim may be correct for logical truth but, as Boolos (1975) has shown, it does not extend to consequence.

Tarski had already come across this problem in his work on the concept of truth in formalized languages (1933). A first shot at the truth-conditions of a universally quantified sentence would be to say that it is true if and only if every particular instance of it is true; but this will not work if there are insufficient constants available, for example, if not every individual has a name. Tarski’s solution was to get round any shortage of genuine constants by treating free variables as roving constants, capable of taking each object of the appropriate type (individuals, relations, and so on) in turn as their ‘value’. Using the idea of a sentential function, in which free variables replace constants, he defined the ‘satisfaction’ (making true) of a sentential function by an assignment of values to its variables. The truth of $(x)Fx$ can then be equated with the universal satisfaction of the sentential function *Fx*.

It was a natural step to apply the same ideas to the definition (F). For brevity, let a ‘model’ of a sentence be an assignment of values that satisfies the sentential function obtained by replacing all the extralogical constants in the sentence by variables. Then, Tarski says, a conclusion follows logically from a number of premises if every model of the premises is a model of the conclusion.

This definition leaves open where to draw the line between logical and extralogical. In particular, it leaves one free to treat ‘thing’ (as in ‘everything *F*s’, ‘something *F*s’) as a logical constant or not. On the second option each assignment of values involves choosing a ‘domain of individuals’ as value for the variable that replaces ‘thing’. The notion of an assignment of values then becomes that of a structure, in the familiar sense of a collection of objects structured by various relations. If too the logical constants are restricted to a mathematically amenable few (for example, $\supset$ instead of ‘if’), the notions of satisfaction and model may be defined in purely set-theoretic terms

(see Model theory). Because of this, the resulting *model-theoretic* conception of consequence has been enthusiastically adopted by many mathematical logicians. Its intimate identification with set theory does, however, expose it to the troubles of that discipline. For, on the prevailing conception, the universe of sets is too large to be a set, and is therefore ineligible to be the domain of any model. For special reasons, first-order logic is unaffected, but the model-theoretic approach to second-order consequence has a question mark over it.

In keeping with the positivism of his day, Tarski wanted nothing to do with modality. (Granted, he uses ‘must’ when formulating (F) as a scheme, but only to indicate that the scheme holds universally; indeed, he stresses that (F) involves no notion more problematic than that of truth.) The non-modal aspect of his definition has been attacked, by Kneale (1961) and subsequently by Etchemendy (1990). A debate is called for, but it will be more fruitful if it asks for what purposes necessity is an essential ingredient of consequence. For example, someone who does not endorse Aristotle’s doctrine of proof and *epistēmē* may well be content with proofs that establish the bare truth of theorems, and it is not obvious that this requires a modal relation of consequence. Again, one motive for developing (say) group theory in the abstract is to derive laws that can be applied to all possible groups. But here a ‘possible group’ does not mean a non-existent structure composed of possibilia, but an actual structure waiting to be recognized as a group (compare with ‘a possible hiding-place’). Once more, a modal conception of consequence is not obviously required.

6 Enthymemes

For a genuinely pre-theoretic notion of consequence one needs to look outside the logic books, and to remember too that a philosopher’s conception of modality is not the only legitimate one: lawyers, scientists and others deal in *real* possibilities, not mere notional logical possibilities. In such circles, arguments take place on the basis of some propositions and some inferences which are common ground and taken for granted; call these an argument’s ‘basis’. But this is not peculiar to everyday argument. A striking example is the predicate calculus, with its built-in presumption that domains of individuals are non-empty (and the corollary that what it holds out as logical consequence fails the test of formality with respect to the extralogical term ‘thing’). Indeed *all* deduction has to proceed on some basis or other, for if every step were challengeable, argument could never get moving.

Historically, adherents of one conception of consequence have tried to exclude any other by the doctrine of the ‘enthymeme’, or incomplete argument. If an argument ‘*P*, so *Q*’ looks sound but does not measure up to the favoured standard, some part of its basis (call it *B*) is declared to be a missing, ‘suppressed’ premise. The original arguer was either incompetent or deluded: their argument should have been, or really was, ‘ P, B, so *Q*’. This expanded version will satisfy the favoured standard, which is thereby vindicated. As well as using this weapon against everyday consequence, logicians have turned it on each other. Traditional logicians use it to claim that all consequence is really syllogistic. Formal logicians of every stripe use it to claim that all necessary consequence is really formal (that is, someone who takes for granted the transitivity of ‘before’ is guilty of suppressing a premise, though someone who takes for granted the transitivity of ‘implies’ is not).

The self-serving character of the enthymeme doctrine is plain. Perhaps what is needed is, rather, an inclusive theory of consequence that will accommodate all kinds of basis for arguments. Let *B* be any basis; then a number of premises imply a conclusion on the basis of *B* if the conclusion belongs to the closure of the premises with respect to *B*. In the spirit of Bolzano, one can go on to develop the general theory of consequence relative to a basis. It needs to be complemented, however, by a quite different kind of discussion, about what bases are appropriate to what purposes and circumstances. In this connection (setting aside any differences over relevance), the broad conceptions of consequence descried in the previous sections can be seen as lumping together a class of eligible bases. Thus Chrysippian consequence covers - more exactly, it is the union of - consequence taken over all bases composed exclusively of analytic propositions and steps. Similarly, Philonian consequence is the union of consequence taken over all bases composed of true propositions and truth-preserving steps, though its paradoxical characteristics suggest that this is not the best way of dealing with so diverse a class.

Consequentialism

Consequentialism assesses the rightness or wrongness of actions in terms of the value of their consequences. The most popular version is act-consequentialism, which states that, of all the actions open to the agent, the right one is that which produces the most good.

Act-consequentialism is at odds with ordinary moral thinking in three respects. First, it seems excessively onerous, because the requirement to make the world a better place would demand all our time and effort; second, it leaves no room for the special duties which we take ourselves to have to those close to us: family, friends and fellow citizens; and third, it might require us, on occasion, to do dreadful things in order to bring about a good result.

Consequentialists standardly try to bring their theory more into line with common thinking by amending the theory in one of two ways. Indirect act-consequentialism holds that we should not necessarily aim to do what is right. We may get closer to making the world the best possible place by behaviour which accords more with ordinary moral thought. Rule-consequentialism holds that an action is right if it is in accordance with a set of rules whose general acceptance would best promote the good. Such rules will bear a fairly close resemblance to the moral rules with which we now operate.

1 Act-consequentialism

Although the term ‘consequentialism’ is a recent coinage - it appears to have first been used in its present sense by Anscombe (1958) - it refers to a type of theory which has a long history. Consequentialism builds on what may seem to be the merest truism, namely that morality is concerned with making the world a better place for all. Consequentialist considerations certainly figure importantly in issues of public policy. Penal, economic or educational programmes are standardly judged by the goodness or badness of their results.

All moral theories offer an account both of the right and of the good. They all tell us, that is, both what makes an action right or wrong, and what kinds of thing are good or valuable. It is characteristic of consequentialist theories to assess whether an action is right in terms of the amount of good it produces (see §4). Deontological ethical theories, by contrast, hold that the right is independent of the good: certain kinds of action are wrong, and others right, independently of the goodness or badness of their consequences (see Deontological ethics; Right and good).

Act-consequentialism, the simplest form of the theory, holds that the right action - the one you should do - is the one which would produce the greatest balance of good over bad consequences; that is, the one which would maximize the good. (Where two or more actions come out equal best, then it is right to do any one of them.) Which action is in fact the right one will depend on what account of the good any particular act-consequentialist theory offers.

A theory of the good is an account of those things which are intrinsically good, good in themselves, and not merely good as a means to something else which is good (see Good, theories of the §2). A visit to the dentist is only extrinsically good, because it leads to healthy teeth and the avoidance of toothache, but it is not in itself a good thing; it is a necessary evil. By far the most popular and influential account of the good within the consequentialist camp is that offered by utilitarianism (see Utilitarianism). On this view, usually known as hedonism or welfarism, the good is pleasure, happiness or wellbeing (see Hedonism; Happiness). The act-utilitarian holds, therefore, that the right action is the one which maximizes happiness.

Many consequentialists reject hedonism. A pioneer in this respect was G.E. Moore (1903), whose theory, somewhat confusingly, used to be referred to as ideal utilitarianism, in contrast to the hedonistic variety (see Moore, G.E. §1). Among the things which have been held to be intrinsically good are knowledge, virtue, beauty, justice, and the flourishing of the environment as a whole. Many of these alternative accounts of the good are pluralist: that is, they claim that there are several different kinds of good thing which cannot all be brought under one head (see Moral pluralism). Pluralist act-consequentialism faces a difficulty. In order to determine which of the possible actions is the right one, agents must be able to rank the outcomes of each action, from the worst to the best. But if there are several distinct values which cannot be reduced to a common measure, how can one kind of value be compared with another in order to produce a definitive ranking? This is the problem of incommensurability of value.

The term ‘consequentialism’, though hallowed by frequent philosophical use, may be misleading since it might naturally be taken to imply that an action itself can have no intrinsic value; its value is all to be found in its consequences. Utilitarianism is indeed committed to this view - for what matters on the utilitarian account is not the nature of the act itself but the pleasure which it produces in anyone affected by it - but it is not an essential feature of consequentialism as such. Some consequentialists wish to leave room for the thought that certain kinds of action, such as lying, cheating, and killing the innocent, are intrinsically bad, while other kinds of act, such as generous, loyal, or just ones, are intrinsically good. Consequentialism can take such values into account in calculating which course of action produces the best results. In deciding whether one course of action is preferable to another, a consequentialist needs to know the total value that would be produced by taking each course of action, and that will include not only the value of the consequences but the value, if any, which attaches to the action itself.

Consequentialism is sometimes described as a teleological theory, because it conceives of a moral theory as setting a goal which we should strive to achieve (see Teleological ethics). The goal which consequentialism sets is to bring about a world containing the greatest balance of good over bad. Such a classification risks confusion, however, since a virtue ethics, such as Aristotle’s, is also usually classified as teleological, yet Aristotle’s theory differs from consequentialism in at least two crucial respects. First, the good at which agents aim, on Aristotle’s view (outlined in *Nicomachean Ethics*), is not the best state of the world, but the good life for humans; agents are to seek to realize distinctively human goods in their own lives. Second, Aristotle’s theory, unlike consequentialism, does not define the right in terms of the good. On the contrary, a full understanding of the good life rests on a prior conception of the right, for an important part of the good life consists in acting rightly (see Aristotle §§21-6; Right and good §2; Virtue ethics).

We also need to distinguish the kind of consequentialism with which we are here concerned from ethical egoism, which is sometimes classified as a consequentialist theory (see Egoism and altruism). Ethical egoism, which holds that the right action is the one which would best promote the agent’s own interests, is structurally similar to consequentialism in that the right action is the one which maximizes a good, in this case, the agent’s own good. What distinguishes egoism from the sort of consequentialism discussed here is that the latter is an *impartial* theory, giving equal weight to each person’s good (see Impartiality).

2 Criticisms of act-consequentialism

How should consequentialists set about deciding what to do? A natural answer is: by calculating, as best they may, what would produce the most good on any particular occasion when they are called upon to act. Of course, lack of time and knowledge limit what they can do by way of calculation, but they must do the best they can. So interpreted, however, act-consequentialism can be criticized for running counter to our intuitive moral convictions in a number of ways.

First, it seems excessively demanding; I shall only be acting rightly in so far as I maximize the good. Given all the bad things in the world, and the fact that few of us do much to improve them, it is clear that, in order to do what act-consequentialism requires, I would have to devote virtually all my energy and resources to making the world a better place (see Help and beneficence §2). This would give me no time or money to pursue my own interests, or even to relax, except to refresh me ready to redouble my moral efforts on the morrow. The degree of self-sacrifice required would make the lives of the saints look self-indulgent. Ordinary morality is surely not as demanding as this; it gives us permission to pursue our own goals, provided that we are not in breach of any of our fundamental duties. Some have proposed, in order to meet this point, that the theory be modified so that an act is right if its consequences are good, or good enough, even if they are not the best. This suggestion has not been widely adopted, for it is usually held that a rational agent will always prefer the greater good to the less.

Second, act-consequentialism appears to leave no place for the duties we take ourselves to have to our family and friends (see Family, ethics and the; Friendship). Such duties are often classified as agent-relative: each of us should help *their own* family and friends, so that the persons to whom the duties are owed vary from agent to agent. Act-consequentialism, however, is an agent-neutral moral theory; the goal at which we should aim does not depend on who the agent is. I should direct my efforts towards those for whom I can do the most good; their relationship to me is irrelevant. Even if act-consequentialism places special value on the cultivation of certain

relationships, such as friendship, this will still not yield a duty of friendship, as traditionally understood. If friendship is a great good, then my duty as a consequentialist is to promote friendship in general between all persons; that will not necessarily require me to give special attention to *my* friends, as distinct from helping others to give special attention to their friends.

Third, if act-consequentialism is too demanding in one respect it seems too permissive in another. For it leaves no room for the thought, central to much ordinary moral thinking, that there are certain constraints on our action, certain kinds of act, such as cheating, torturing and killing, which we ought not to contemplate, even if acting in one of these forbidden ways would maximize the good. The end, as we often say, does not justify the means. Once again, constraints seem to be agent-relative. Each of us is required not to kill or torture the innocent *ourselves* even if, by doing so, we could prevent two such tortures or killings.

3 Indirect act-consequentialism

Because it generates these counter-intuitive results, few consequentialists hold that agents should decide what to do by asking what will produce the best results. There are two theories which offer a less direct link between the overall goal of making things go as well as possible and how one should decide to act on any particular occasion. The first of these is known as indirect act-consequentialism. It retains the claim that the right action is the one with the best consequences, but denies that the virtuous agent need be guided directly by consequentialist thoughts when deciding how to act.

Indirect act-consequentialism builds on the thought that we do not necessarily hit the target if we aim directly at it. The gunner must make allowances for wind, gravity and poorly aligned sights; the moralist may have to direct our thoughts away from the goal if we are to achieve it. Act-consequentialism, on this view, tells us what the target is, but not how to hit it. It is not itself a good guide to action for a number of reasons: the calculations are tricky and time-consuming; we may be tempted to skew the results in our favour; doing the right action may require us to go against dispositions which are both deeply rooted and generally useful. So we may actually do better, in terms of achieving the goals which consequentialism sets us, if we do not aim to do what is right, but follow a few fairly simple moral rules of the traditional type, or encourage within ourselves the development of dispositions, such as kindness and loyalty, which will normally lead us to act in beneficial ways. In adopting such rules, or developing such dispositions, we know that we will sometimes act wrongly when we could, perhaps, have acted rightly. Yet we may still get closer, in the long run, to achieving the consequentialist goal than we would have if we had attempted to aim at it directly.

Some indirect act-consequentialists go further. Since we make better decisions if we eschew consequentialist calculations, it might be best if we rejected consequentialism. It seems possible that agents might behave worse, in consequentialist terms, if they were taught the truth of consequentialism than if they were brought up to believe some other moral theory. In which case consequentialists would do well to prevent its truth being generally known. Opponents see this position as incoherent. If the adoption of consequentialism demands its suppression then in what sense can we adopt it? How could a society be said to be governed by a moral code if no-one in that society believed it?

4 Rule-consequentialism

The second alternative to direct act-consequentialism is rule-consequentialism, which offers a more substantive role for moral rules or principles. Individual acts are judged right or wrong by reference to the rules; the rules, but not the individual acts, are judged by the results of accepting them. The right action is, roughly, the one that is in conformity with a set of moral rules which, if generally accepted, would tend to produce better results than any other set of viable rules we might accept. Rule-consequentialism differs from indirect act-consequentialism in two ways. It maintains that each decision should be guided by thoughts about which action is the right one, and denies that the right action is necessarily the one with the best results. In deciding which rules to accept we should bear in mind that the rules need to be clear, reasonably simple and not too difficult to comply with, given human nature. If they meet these requirements, it is likely that such rules will not be too dissimilar to our present ones.

Rule-consequentialism might be a plausible moral theory, but should it properly be seen as a form of consequentialism? It apparently abandons a central tenet of consequentialism: the claim that our goal should be to

maximize the good. The rule I should follow, on this view, is the one that *would* have better consequences, if generally accepted, than any other rule. If it is not, in fact, generally accepted, then in following it I may not get as close to maximizing the good as I would if I followed some other policy. For that reason, perhaps, act-consequentialism has remained most popular among defenders of the theory, despite its difficulties.

Conservation principles

In antiquity 'self-evident' principles were used to argue for the conservation of certain quantities. The concept of quantitative conservation laws, such as those of mass and energy, is of much later origin. Even prior to the development of modern mechanics, symmetries were employed to solve some dynamical problems. The relation between conserved quantities and symmetries has come to play a central role in the physical sciences. Conservation laws may reflect as much about the way the human mind organizes the phenomena of the world as they do about physical reality itself.

One can distinguish between broad metaphysical principles of conservation and empirical conservation laws. Here we shall be concerned mainly with the latter. Historically, the development of each concept influenced that of the other. In the sixth and fifth centuries BC, several Greek thinkers (Thales, Anaximander, Anaximenes, Empedocles, Leucippus and Democritus) promulgated a range of materialistic philosophies, which included a belief that all substances in the cosmos are derived from some single substrate (or, at most, from a few of them) or that matter has an atomistic structure (see Matter §1). Like these ancient materialists, Antoine Lavoisier (1743-94) in his *Elements of Chemistry* (1789) took it as axiomatic that in natural processes no matter is ever created or destroyed. John Dalton's (1766-1844) atomic hypothesis, based on 'ultimate particles' of matter, also assumed conservation of matter or, in modern terminology, of mass. René Descartes (1596-1650), on basically theological grounds, adumbrated a law of conservation of momentum, while he and Christiaan Huygens (1629-95) had a proper conception of the law of inertia which is closely related to momentum conservation. However, it was only with Isaac Newton's (1642-1727) *Principia* (1687) that mechanics was provided with a sufficiently complete and consistent dynamical scheme from which conservation laws could be derived. In modern terminology, by a conserved quantity we mean one that is a constant in time by virtue of the dynamical equations of motion. The elegant formulations of classical mechanics by Leonhard Euler (1707-83), Joseph-Louis Lagrange (1736-1813) and Pierre-Simon Laplace (1749-1827) allowed one to find the conserved quantity corresponding to an invariance property of a mechanical system (see Mechanics, classical §5). As an example, the invariance of a physical system under rotation about some axis fixed in space implies the conservation of angular momentum about that axis. Given the dynamics, one then derives certain invariances and conservation laws.

The law of conservation of energy is one of the most important in physics. This law is very broad and extends far beyond mechanics. The physicists Benjamin Thompson (1753-1814) and James Joule (1818-89), and the chemist Humphrey Davy (1778-1829), were instrumental in demonstrating the interconvertibility of mechanical energy and heat. The first formulation of the concept of energy conservation was given by the physician and physicist Julius von Mayer (1814-78), although he received proper recognition only after Hermann von Helmholtz (1821- 94) rediscovered his work. Albert Einstein (1879-1955) unified the conservation of mass and of energy into a single law by arguing for the equivalence, or interchangeability, of mass and energy (see Einstein, A. §2). As ever more forms of energy are included in a generalization of the law of conservation of energy, the status of that law becomes almost definitional (but still extremely useful). In fact, Émile Meyerson held that there are principles of lawfulness and of causality which reflect basic and universal characteristics of human thought and understanding. This suggests that our various conservation laws may be rooted as much in the human mind as they are in any external reality.

Much of the fundamental work in twentieth-century theoretical physics is based on an intimate connection between conserved quantities and the symmetries of physical systems. In common usage the term 'symmetry' often refers to a certain pleasing proportion or balance. However, here we are concerned with a technical sense of this term, as in geometrical symmetries or in the crystalline symmetry of a snowflake. As an illustration, a plane equilateral triangle is left invariant under successive rotations of 120 degrees about an axis perpendicular to the plane of the triangle and through its centre. The figure looks the same after the rotation as before. Similarly, we can consider those transformations that leave unchanged the *form* of the mathematical equations describing a physical system. This connection between symmetries and conserved quantities had long been familiar in classical Lagrangian mechanics, but the mathematician Emmy Noether (1882-1935) proved a general result that continues to hold in relativity and in quantum theory. Just as invariance under displacements in space and time yields energy and momentum conservation, so, for example, what is termed the 'internal' symmetry of gauge invariance (a

mathematical operation that leaves Maxwell’s equations for electrodynamics unchanged) leads to the conservation of electrical charge. Another type of gauge invariance (a change of the arbitrary phase of the wave function in the Schrödinger equation) implies conservation of probability in quantum mechanics. What are termed higher symmetries can account for other conservation laws, such as that of baryon (or nucleon) number in elementary-particle physics. In a sense, physics has come full circle, building into theories those symmetries that will ensure certain conservation laws. When we have a complete dynamics, we use it to derive conservation laws. When searching for new theories, symmetries are a guide to discovery (see Electrodynamics; Field theory, quantum).

Conservatism

Conservatism is an approach to human affairs which mistrusts both a priori reasoning and revolution, preferring to put its trust in experience and in the gradual improvement of tried and tested arrangements. As a conscious statement of position, it dates from the reaction of Burke and de Maistre to the Enlightenment and Revolutionary thought and practices in the eighteenth century. Its roots, however, go far deeper. From Plato, conservatives derive a sense of the complexity and danger of human nature, although they reject emphatically his belief in the desirability of philosophical governance. From Aristotle, conservatives derive their sense of the need for practical experience in judging both moral and political matters, and their understanding of the role of tradition in inculcating habits of virtue and wisdom in the young.

Against Plato, conservatives prefer the limited government advocated by Hobbes, because of their belief in the ignorance and corruptibility of rulers, and because of their wish to encourage the self-reliance of subjects. They do, however, reject any conception of a social contract. In this, they follow de Maistre, who argued that creatures with the institutions and reactions necessary to form a social contract will already be in a society and hence have no need of such a thing.

While de Maistre emphasized the terror underlying political power, more characteristic of modern Anglo-Saxon conservatism is the position of Burke. For Burke, a good constitution is one adorned with 'pleasing illusions' to make 'power gentle and obedience *liberal'. It is also one which dissipates power in a society through autonomous institutions independent of the state. For both these reasons the communist regimes of eastern Europe could not be defended by conservatives, even though for a time they represented a form of social order.*

While conservatism is not antithetical to the free market, and while the market embodies virtues the conservative will approve of, for the conservative the market needs to be supplemented by the morality, the institutions and the authority necessary to sustain it. Human beings are by nature political, and also inevitably derive their identity from the society to which they belong. Our sense of self is established through our family relationships and also through the wider recognition and apportionment of roles we achieve in the public world beyond the family. According to Hegel, who since Aristotle has written most profoundly on the interplay of the private and the public in human life, both family and the public world of civil society need to be sustained through the authority of the state. On the other hand, the distinctions between family, civil society and the state need to be maintained against the characteristically modern tendency to treat them collectively. In his insistence both on authority and on the checks and balances needed in a good society, Hegel may be said to be the most articulate and systematic of conservative thinkers.

Conservatism has been much criticized for its tendency towards complacency and to accept the status quo even when it is unacceptable. However, in its stress on the imperfectibility of human nature and on the dangers of wholesale revolution, it may be said to be more realistic than its opponents. Conservatives can also be quite content with the claim that societies animated by conservative political structures have been more successful morally and materially than socialist or liberal societies. This claim they believe to be true, and it is a fundamental aspect of their position that the dispute between them and their opponents is, at bottom, an empirical one.

1 The conservative temper

Many strands of thought make up conservatism, and thinkers who are regarded as conservative have held a wide variety of opinions on many crucial issues, both philosophical and political. The protean and, to the intellectual mind, untidy character of conservatism is, however, part of its essence. Indeed, it is an important aspect of what distinguishes conservatism from other ideologies, or, as conservatives would say, from ideologies. For conservatism is an approach to human and, more specifically, to political affairs which mistrusts the power of human reason. Its temper is sceptical and empirical. It places more faith in tried and tested arrangements than in ideas, however brilliant. It recognizes the extent to which individuals are situated within their societies, and the extent to which societies are fashioned by their histories. Conservatism is also acutely conscious of the flaws in human nature, as well as its potential for good, and of the way in which civilized life depends on a context of order and tradition.

It has rightly been said that prior to the Reformation, it was impossible to distinguish conservatism in politics, not because none existed but because there was nothing else. However, even between the time of Luther and that of the French Revolution, while we can certainly discern conservative themes in writers such as Hobbes, Swift, Pascal and Hume, it is not until Edmund Burke's *Reflections on the Revolution in France* (1790) and Joseph de Maistre's *Considérations sur la France (Considerations on France)* (1797) that we find comprehensive and self-conscious statements of a conservative position. It is no coincidence that both these impassioned diatribes were conceived as reactions to what their authors perceived as a deadly threat to the established order of society, and in de Maistre's case, to the divine order as well.

The conservative position is one that is better unarticulated not, as its opponents might insist, because it is intellectually threadbare, but because its preference is for the harmony which arises from an unquestioning and untroubled acceptance of settled ways of doing things. In making articulate what is better left unsaid, conservatism is, from its own point of view, in danger of lapsing into ideology, into the erection of principle and dogma over practice and habit. As we will see, neither de Maistre nor certain modern conservatives have proved immune to this temptation.

2 Plato and Aristotle

While explicit conservatism may be a characteristically modern phenomenon, the intellectual roots of much conservatism can be found in the thoughts of Plato and, more particularly, Aristotle. From Plato conservatives derive a keen sense of the dividedness of human nature. For most conservatives would assuredly recognize the image in *Phaedrus* of the soul consisting of a charioteer struggling to harness together a good horse and a bad horse (*c*.366-360 BC; 253c-). For conservatives one incontrovertible lesson of history is the danger of licence and anarchy, and the human and political folly of the romanticism which would do away with political order in the name of freedom or even reason. Individuals do not have reason enough to order their own affairs, nor even do whole societies starting from scratch; and freedom, in practice, is too often freedom for one person's bad horse to do violence both to his or her own better nature and to those around. Thus conservatives would sympathize with the Platonic insistence on the need for order provided by a strong state, as featured in both *Republic* (*c*.380-367 BC) and *Laws* (*c*.360-347 BC) (see Plato §§14,17).

Conservatives would, however, have rather less sympathy with other aspects of Platonic thought. Conservatism is not committed to the view that decline is inevitable, nor indeed to the myth of a past golden age. Being more aware than non-conservatives of the problems involved in change is not synonymous with an obdurate refusal of all reform. Indeed, wholeheartedly rejecting the central Platonic doctrine of the possibility of infinitely enlightened rulers, conservatism must embrace mechanisms for gradual reforms necessitated by errors of policy, errors often visible only after experience of the effects of policy, and particularly to the ruled who suffer most from the effects.

Central to conservatism is the belief that even the best-intentioned action can have unexpected and undesired consequences. The ramifications of the unintended consequences are the greater when the actions in question are policies whose effects will bear upon a whole society. Even the cleverest and most beneficent agencies will inevitably be unable to predict all the effects of their policies in advance. Because of their inevitable ignorance and because, in any case, they are unlikely to remain completely uncorrupted by power, in contrast to Plato conservatives favour a system in which the scope of the actions of rulers is limited, and in which revision and reform is a real possibility.

Overall, in fact, the empiricism of Aristotle is far more congenial to conservatives than the rationalism of Plato. For Aristotle, both ethical enquiry and politics are areas in which there is no substitute for the wisdom which derives jointly from experience and the patient cultivation of good habits. If politics were simply a matter of cleverness, then we would expect to be able to learn about it from sophists, who profess to be able to teach it, but who are far from being able to practise it to good effect. We cannot learn about medicine or painting from people who are not doctors or artists. In like manner, the would-be legislator needs experience of life and politics, over and above intelligence; guidance is needed also from those versed in the intricacies of human affairs, rather than from the merely clever. Moreover:

> The soul of the student must first have been cultivated by means of habits for noble joy and noble hatred, like

> earth which is to nourish the seed. For he who lives as passion directs will not hear argument that dissuades him nor understand it if he does.
>
> (*Nichomachean Ethics* 1179,b,25-6)

Aristotle's assumption (see Aristotle §§27, 28), in contrast to that of moral educators in the romantic and rationalist traditions, who would have even young children submit all their moral beliefs to critical scrutiny, is that moral reasoning can proceed properly only on the basis of good habits, already ingested and ingrained. Aristotle's clear assumption, like that of the conservative, is that moral and political virtues emerge as the fruits of experience, and are passed on to the newcomer brought up within the tradition which recognizes experience as the wisdom of the past. To the newcomer this process of transmission is initially an unthinking one, purely a matter of habit.

As well as his moral conservatism, Aristotle insisted on hierarchies of talent and ability, albeit in a less rigid and doctrinaire manner that Plato. He also argued strongly that justice is not equality, but the giving to each of what each are owed. It is hard to think of any conservative dissenting from Aristotle's inegalitarianism, firmly based as it is in facts about human nature and in the actual development of history and culture. Nor would a conservative be likely to favour Plato's holist state over Aristotle's more limited type of rule in which, although the state is logically prior to the individual, private property, the family and other activities independent of the state are clearly envisaged.

3 Hobbes

Conservatives are dispositionally inclined towards a Hobbesian polity for at least two reasons. First, a strong government is needed in order to protect individuals and communities against injustice and the depredations of the strong, and to turn what would otherwise be a war of all against all into a settled, peaceful existence (see Hobbes, T. §6). Second, limited government is favoured both because of the ignorance and corruptibility of rulers and also to encourage the self-reliance of subjects.

Where, however, conservatives depart from Hobbes and all liberals of a contractarian sort is on the notion of a social contract (see Liberalism §5). A contract, as even Hobbes admits, is, *in extremis*, defeasible (Hobbes 1651). Whereas if, following Burke, conservatives see life as a partnership between the living, the dead and the unborn, it is not a partnership in which we, the living, can be absolved from our duties to our partners, if only because they are not here to release us. In any case, for conservatives the very idea of non-social animals - or as they view them, savages fleeing from the war of all against all - coming together to contract is a nonsense; such beings could never construct a system depending on the mutual recognition of obligations and enforcement of promises. Meanwhile, those creatures who could enact a social contract, with the rewarding, punishing and respecting of each other's rights and freedoms which such a notion requires, are already in a society, and so have no need of a primeval contract (de Maistre 1797) (see Contractarianism §§2-6).

4 De Maistre and Burke

De Maistre, whose criticism of the social contract is given above, held that society is not made by man, weak as he is and his 'reason' a feeble pretence, but by God. Thus, any attack on the social order amounts to a blasphemy. Furthermore, society is held together only by the executioner, 'the terror of human society and the tie that holds it together'. This is conservatism as reactionary ideology. De Maistre takes every cherished doctrine of the Enlightenment and turns it on its head. In so doing, he shows the same cavalier disregard for human life as those he attacks, to such a degree that he is led to compliment the Jacobins on the grounds that they, unlike their liberal-minded predecessors, at least killed people and restored order of a sort.

In so arguing, de Maistre falsifies what, since Burke, has become a central tenet of Anglo-Saxon conservatism; that the main defence against anarchy and against the war of all against all is not the brute power of the state. Burke had no more illusions about human motivation or ability than de Maistre, but he saw that sentiment had to be added to power in order for a state to become a community, tolerable for all to live in. Burke, like de Maistre, believed that 'no great human institution results from deliberation' but is the result of evaluation over time in ways often undreamt of by its founders, and also that 'human works are fragile in proportion to.… the degree to which science and reasoning' have been involved in their construction (1797: 57). Both men pour scorn on the

attempt to formulate a constitution or a bill of rights which is not simply an articulation of existing practice, and even more upon the characteristically modern delusion that liberty, rather than its opposite, can be secured by such a procedure. Furthermore, de Maistre's adage that 'threads which can be broken by a child at play can nevertheless be joined to form a cable capable of supporting the anchor of a great vessel' (1797: 75) is entirely in the spirit of Burkean conservatism, in both its positive and negative aspects; negatively, that seemingly trivial criticism can undermine the spirit of a great enterprise; positively, that what binds a great society need not, indeed must not, seem onerous, or the cause is dead.

And it is here that Burke and de Maistre part company. For Burke, and those of his followers supporting the tradition of Anglo-Saxon conservatism, what is crucial in a successful constitution are 'the pleasing illusions' which make 'power gentle and obedience liberal', which harmonize 'the different shades of life and which, by a bland assimilation' incorporate 'into politics the sentiments which beautify and soften private society'. Revolutions tear off all this 'decent drapery of life' and expose our 'naked shivering nature'.

> On this scheme of things, a king is but a man; a queen is but a woman; a woman is but an animal; and an animal not of the highest order. All homage paid to the sex in general as such, and without distinct views, is to be regarded as romance and folly. Regicide, and parricide, and sacrilege, are but fictions of superstition, corrupting jurisprudence by destroying its simplicity. The murder of a king, or a queen, or a bishop, or a father are only common homicide; and if the people are by any chance, or in any way, gainers by it, a sort of homicide much the most pardonable, and into which we ought not to make too severe a scrutiny.
>
> (Burke 1790: 171)

Burke goes on to contrast this conservatism with the barbarous philosophy, the offspring of cold hearts and muddy understanding, in which 'laws are to be supported only by their own terrors' (see Burke, E.)

De Maistre was certainly as guilty as some of his opponents of subscribing to a barbarous philosophy, and to that extent should be regarded as outside the conservative mainstream. Moreover, the spirit of what Burke says need not require sentiment invested in any particular form of government; only that it is genuinely invested somewhere, or else government - and human life as a whole - will reveal itself in its most repulsive and reductive form. It is thus clear that conservatism does not sanction any form of established power. In particular, it would not sanction a form of established power incapable of sustaining public affection, as was the case in eastern Europe during the Cold War. There the Communist party was the only authority and only power, running every aspect of society through a series of front institutions in whose legitimacy and independence few believed.

Even if the eastern European dictatorships had commanded more public affection than they did, and however long lasting and successful they had been, they would not in any case have been acceptable to conservatives. Following Burke, conservatives put considerable stress on the necessity for autonomous institutions and sources of power, so as to balance state power and to mitigate the consequences of centralized ignorance. It is here that there is an overlap between conservatism and the classical liberalism of Adam Smith and his followers (see Liberalism §2; Smith, A. §4).

5 Conservatism and the market

Adam Smith's model of the free market is based on the assumption that the most efficient way of organizing an economy is one that has evolved without planning, and which runs best without interference from the centre. It is impossible to know how agents in a large society will act economically before they actually engage in market transactions. If there are many entrepreneurs and producers there is a greater likelihood of real needs and desires being met than if there is only one agency of production. Those producers who, by a combination of luck and design, manage to tap into actual demand will benefit; and so will consumers who, from the range of goods and services offered, will pick those which satisfy their wants at the cheapest price. In Smith's view, those of us in capitalist societies have stumbled on a system in which producers and consumers are enabled to benefit each other, and which will produce both a measure of economic stability and productive drive, even though each individual in the system acts only on his or her private desires (to maximize profit, to purchase the best at the cheapest price). The system will, however, break down if central agencies attempt to restrict what is, in effect, the flow of information to and from producers and consumers, and so disturb its natural albeit unplanned tendency towards equilibrium.

Both the evolutionary aspect and the anti-statism of Smithian economic theory is likely to appeal to conservatives, who are also aware of the limitations of planning. But a true conservative would never, as Hayek did, utter any general edict against planning, even planning of a centralized sort (see Hayek, F.A. von §3). Making anti-planning into a principle or economic liberalism into an ideology offends the pragmatic and sceptical temper of the true conservative, who could cheerfully admit a role for state planning and even for economic interference were such things necessary, as in the modern world they no doubt are in order to make one's country, as Burke would have it, 'lovely' to one's compatriots. As Michael Oakeshott put it:

> A plan to resist all planning may be better than its opposite, but it belongs to the same style of politics. And only in a society already deeply infected with Rationalism will the conversion of the traditional resources of resistance to the tyranny of Rationalism into a self-conscious ideology be considered a strengthening of those resources. It seems that now, in order to participate in politics and expect a hearing, it is necessary to have, in the strict sense, a doctrine; not to have a doctrine appears frivolous, even disreputable. And the sanctity, which in some societies was the property of a politics piously attached to traditional ways, has now come to belong exclusively to Rationalist politics.
>
> (Oakeshott 1962: 21-2)

For Oakeshott, conservatism is to be contrasted principally with Rationalism, which is the belief that politics is to be understood in terms of getting things done, of achieving ends laid down by predetermined blueprints. For Oakeshott, this approach embodies the dual fallacy of thinking first that ends can be laid down independently of the means one consider appropriate in the light of one's way of life, and second, of failing to appreciate that the most important things in life are ends in themselves, worth having and cherishing for what they are, not for what they enable one to achieve. One of the deformations of the modern world is the introduction of methods and ideas appropriate to instrumental rationality into areas where they are inappropriate, such as the law, education and the arts. Above all, the introduction of means-end thinking is undesirable in connection with the state itself, not least because we have no choice in regard to membership of it (see Oakeshott, M.J. §3).

For Oakeshottian conservatism, politics should be seen in terms of a people elaborating ways of living together in the light of its particular history and traditions, and because of the compulsion involved, governmental and political intervention should be as light as possible. Political activity should not be seen as an enterprise driven by the pursuit of universally determinable extrinsic goals, such as equality or the elimination of poverty. To those who think otherwise, it might be pointed out that even if what is said is couched in the abstract language of universal rights, what will at any given point count as equality or the elimination of poverty will depend very much on the thought and practice of the time (see Tradition and traditionalism).

Much of the transformation of politics into enterprise and instrument has occurred because of collectivist approaches to institutions; much has happened because of market-led thinking. It is a moot point as to whether classical liberals would have favoured the prevalent instrumentalist view of politics and institutions, which Oakeshott criticizes. Adam Smith himself believed the weakening of traditional allegiances to be one of the 'inconveniences' of market societies. He, along with more recent neo-liberals such as Hayek, also recognized the need for a strong, if minimal, state to enforce contracts and to provide the social stability within which the market can operate. Thus, the supposed conflict between economic liberalism and conservatism often cited as a criticism of Mrs Thatcher's project of a strong national state combined with a free market does not appear as such in the works of her mentors. Nevertheless, from the conservative point of view economic liberalism certainly needs supplementation if it is to provide an adequate account either of man or of society.

6 Hegel

At this point, conservatives will point to a need to generalize de Maistre's criticism of social contract theories of the state. The social contract is a nonsense because it has to assume that what it purports to set up already exists. But equally nonsensical is the idea of the abstract ahistorical individual rational agents envisaged in so much Kantian and post-Kantian moral philosophy, the self who (in Rawls' terms) is prior to the ends affirmed by it. As F.H. Bradley put it: 'the man into whose essence his community with others does not enter, does not include relations to others in his very being, is a fiction' (1876 (1927): 168). Here Bradley is echoing Hegel, who in turn is drawing on de Maistre and Burke and, more remotely, Aristotle (see Bradley, F.H.).

For Aristotle, man is, by nature, a political animal, bound by his very identity to family and city. In Hegel’s hands this involves recognition that we are born into a network of relationships and obligations, which we did not choose, and to which we owe indissoluble debts of piety. Our sense of self arises first in the reciprocity involved in our natural family, and it is then extended into the public world of mutual but impersonal recognition through which we escape the war of all against all. (For Hegel this is civil society, in which is resolved the life and death struggle of master and slave.) As our identity as self-conscious agents is only made possible by this social network, in being disloyal to it, we are disloyal to the very self whose emancipation we vainly seek in our disloyalty. But while it is through the family and the institutions of civil society that we all derive our initial identity and the possibility of developing a life and career in the public world, they in turn owe their existence and wellbeing to an all-protecting state (Hegel 1833) (see Hegel, G.W.F. §8).

Against the liberals, then, Hegel will insist on the priority of the state and its independence from individual, family and the institutions of civil society. Like Burke and de Maistre, he believes that order, family and civil society will collapse without the state, and without cultivation of habits of obedience to the state (and, particularly, of loyalty to the sovereign). On the other hand, collectivists, who include individual, family and civil society within the state, forget the state’s *raison d’être* and the way its role and the respect it warrants demand that it should be above particularity, faction and caprice. While Hegel was not a democrat, neither was he a totalitarian. He argued for the personal, and no doubt in practice unequal, accumulation of capital as a means to protect individual and family and to assure generational continuity; for the welfare state as a means of ensuring cooperation from subjects; and for autonomous institutions against the might of the executive. In this intimate and delicate balancing of individual freedom and state power, the insistence on both authority and on checks and balances, Hegel escapes the one-sidedness of liberals and collectivists alike, and at the same time lays claim to be regarded as the most subtle and far-reaching of conservative thinkers.

7 An assessment of conservatism

While a fully expounded Hegelian conservatism contains within itself the resources to answer many of the objections which can be raised to a theoretical conservatism, in practice those who see their actual society riddled with defects and inadequacies are likely to be impatient with the temperamental resistance to change which they find in Burke and his followers in real politics. Furthermore, the stress on human ignorance and on the wisdom of generations - which would not get a hearing in other fields of endeavour - are too often simply an evasion of the hard task of shaking ourselves out of our complacency and working hard to do things better. To its critics, when faced with what they see as its blindness to pressing human problems, conservatism looks like little more than lazy self-interest bolstered by rhetoric and obscurantism.

It is certainly true that conservatism, in certain circumstances, will tend to uphold hierarchies and social distinctions. Conservatism is certainly not committed to egalitarianism, believing as it does in the right of individuals to make their own way through life and to benefit or not accordingly. Freedom of this sort is an important concomitant of the belief common to conservatives and classical liberals alike that individuals rather than the state are the best judges of their own interests. It is also an aspect of the traditional virtues of self-reliance and responsibility to family, qualities which conservatives also stress. But while not committed to equality, as we saw with Hegel, and in contrast to *laissez-faire* liberalism there is nothing in conservatism *per se* to rule out welfarism up to a point. It may indeed be a required part of life in a society that has any claim to be a community deserving of the allegiance of its members, something which is of great importance to conservatives.

None the less, there is no denying that in so far as it does not aim at egalitarianism and regards the means necessary to produce such an aim as likely to cause far more harm than good (and less equality, if the experiences of the French and Russian revolutions are any guide), conservatism does sometimes uphold hierarchies or inequalities. But it must be emphasized that it does not, and will not, uphold *all* or *any* hierarchies. In particular, precisely because of its belief in political ignorance and the imperfectibility of men, especially rulers, conservatism will not uphold totalitarian hierarchies (see Totalitarianism). It will also, in Aristotelian mode, assert that in matters of morality and politics, in contrast to natural science, there are no special experts. Rather, in these areas the experience of the whole of mankind over generations is the main source of moral knowledge, against which should be balanced the pretensions of particular groups of people to moral expertise, however clever they are in their own fields.

As already stated, conservatism should not be identified with blind or dogmatic reaction. Far from being opposed to reform, the principle of reform is central to conservatism, and follows from its scepticism and empiricism regarding human affairs. If obvious abuses exist, then principles and policies must be modified to accommodate improvement. But the modifications must be suitably cautious and their effects monitored. Ancient institutions should be treated with respect, because they embody a kind of tacit wisdom. Because of their ignorance about the way things work and the effects of change, conservatives, although open to reform, are wary of large-scale upsets of what is working reasonably well. And they tend to prefer the tolerable, and even the tolerably bad, to the promise of an unknown and untried good.

Conservatives have no principled objection to a welfare state, providing it allows plenty of room for autonomous institutions and initiatives. But they are more aware than their socialist opponents of the tendency for welfare systems to stifle initiative and self-reliance, and are also more sensitive to bureaucratic bossiness and the inborn tendency of bureaucracies to serve themselves first and their clients second.

Perhaps in the end the issue between conservatives and their political opponents, whether liberal or socialist, is an empirical one. Against socialists, conservatives argue, plausibly enough, that societies with autonomous institutions and unplanned economies have done rather better for all than those with centralized planning and large bureaucracies. Against classical liberals, conservatives will point to the constant splintering of a society which encourages too much choice and diversity, and to the need in a coherent society for a sense of tradition and a deference to generally recognized authority. If these points can be adequately argued, conservatives can rebut the argument commonly made against them that in their resistance to change they are motivated primarily by self-interest. And if this form of argument seems to make the choice for conservatism rest in part on empirical considerations, this will not unsettle conservatives, for their claim is that their position is rooted in a better understanding of human nature and human history than those of their opponents.

Constant de Rebecque, Henri-Benjamin (1767-1830)

Benjamin Constant combined the activities of a religious historian, autobiographer and novelist with a career as a political theorist and politician. Constant's intellectual outlook was shaped by French Enlightenment thought and two years spent at Edinburgh University in 1783-5 added experience of observing the British government and constitution at work. Through all of Constant's writings runs a consistent theme: the necessity of safeguarding the freedom of the individual in modern society. At the end of his life he summed up his liberalism thus: 'Freedom in all things, in religion, philosophy, literature, industry and politics. And by freedom I mean the triumph of the individual both over an authority that would wish to govern by despotic means and over the masses who would claim the right to make a minority subservient to a majority' (1957: 835). Constant's political activity and his writings, which some consider prophetic of the growth of modern totalitarian regimes, have been influential in the development of liberal thought in Europe and the USA.

1 Political activity and thought

The thought of Henri-Benjamin Constant de Rebecque, known as Benjamin Constant (born Lausanne, Switzerland, died Paris) needs to be seen against the background both of his complex and subtle mind - ever sceptical and alive to paradox and ambiguity in all human transactions - and his long observation of the abuse of political power during one of the most turbulent periods of French history. Even during his childhood, Constant had experienced political oppression in Lausanne under the rule of the Bernese, and this instilled in him a lifelong libertarianism. This was reinforced by six years as chamberlain at the court of the Duke of Brunswick, during which time his sympathies veered towards Jacobinism. In Paris after *Thermidor* - and under the influence of Germaine de Staël, with whom he had a long and stormy liaison - Constant tried to bring about the establishment of a moderate republican government in France, using pamphlets and, subsequently, his role as a member of Bonaparte's Tribunate. This remained his ideal during his long period of opposition to the despotism of Napoleon. After twelve years of enforced political inactivity and self-imposed exile in Germany, he sought a political career during the first Restoration and then, notoriously, collaborated with Napoleon during the Hundred Days of 1815. Despite criticism of his action, Constant maintained that the personality of a head of state was of little importance; the ex-dictator's declared intention to act henceforth as a constitutional monarch made him preferable to a restored, autocratic and repressive Bourbon. During his last years, Constant became unofficial leader of left-wing liberals in the French Assembly and one of its greatest orators, campaigning for such causes as press freedom and the abolition of slavery. The July Revolution of 1830, in which he was an important figure, saw the (short-lived) triumph of many of Constant's ideals.

Constant's political thought therefore was not shaped by abstract speculation alone. It developed out of opposition to the cult of antiquity prevalent in eighteenth-century France, and in particular to Jean-Jacques Rousseau's idealization of the small Greek city state. For Constant, Rousseau's notion of the supremacy of the general will over the will of the individual as set out in his *Du Contrat social (The Social Contract)* (1762) and his notorious ban on atheism led inexorably to a tyranny such as had been seen during Robespierre's Terror (see General will §2; Rousseau, J.-J. §3). France had experienced a police state that felt justified in interfering in the lives of individual citizens and even in attempting to invade the inner sanctum of private thoughts and beliefs. Such a view of the individual's relationship with society was regressive and anachronistic, ignoring more than 2,000 years of human development. What may have been appropriate for the Greek *polis* in antiquity was certainly no longer so in the modern world, where personal independence and privacy had become essential in large commerce-based societies. These views, set out in *De la Liberté des anciens comparée à celle des modernes (Freedom in Antiquity Compared With Freedom in the Modern Age)* (1820), drew a clear distinction between freedom in the ancient world and modern freedom. In Constant's memory were Robespierre's communitarian rhetoric and exaltation of Spartan virtues, which demonstrated the dangers of re-establishing a form of society and social relationships where there were no clear boundaries between the public and private spheres. Where the supposed demands of the community were allowed precedence over individual rights, anything might be permissible in the name of the general good. He felt the same concern when it came to scientifically organized utopias of the future, such as that of the Saint-Simonians, which promised greater productivity and human happiness (see Saint-Simon, C. de; Utopianism).

Freedom in modern times demanded clearly defined areas where government interference was not allowed. Not only did the essential right to privacy of the individual need to be protected, due legal processes had to be scrupulously respected and preserved at all times as a bulwark for the individual against arbitrary persecution by an authoritarian government. Yet the Constant who steadfastly defended individual liberty and privacy, so abused by the Jacobins during the Revolution, nevertheless held throughout his career to the ideals of 1789: egalitarianism (as far as the rights of individuals, nations and races were concerned), religious toleration (despite the bitter anticlericalism of his own youth), absolute freedom of speech and of the press, and representative institutions which would be a vehicle for the exercise of popular sovereignty.

Constant's opposition to the usurper and dictator Napoleon, so powerfully expressed in *De l'Esprit de conquête et de l'usurpation (On the Spirit of Conquest and Usurpation)* (1814), was based on the same philosophical grounds. Caesarism, that is, rule by a military dictatorship that consciously echoed the republics of Graeco-Roman antiquity, was as much a brutalizing anachronism as Robespierre's Terror. Wars of conquest by a tyrannical demagogue were the norm in antiquity, but were out of tune with a modern world based on industry, banking and commerce, where peace, tolerance and justice were the order of the day. The *res publica* of antiquity had been replaced as the focus of importance by private pursuits and needs. 'The least government [is] the best government', Constant had written under the Directory, anticipating the thinking of modern liberals for whom the legitimate spheres of government activity should be limited to national defence and the maintenance of law and order (see Liberalism §2).

Individual citizens with their private concerns and activities and their inalienable right to own property, to enjoy personal security, and to have freedom of self-expression, of belief and of movement should be expected to play no greater role in the running of the state than that of casting their vote and choosing their representative in a governing assembly. Gone was the claustrophobic world of the small city state so beloved of Rousseau, where every citizen played a direct role in popular democracy and people could legitimately involve themselves in everyone else's views and business. In its place Constant proposed a constitutional monarchy on the British model, with an essentially figurehead monarch and a bicameral assembly comprising an upper hereditary body, limited in its powers and ensuring stability, continuity and moderation, and an elected lower chamber reflecting the views and life of a society in constant evolution.

2 Religious thought

In a well-known fragment of an unpublished Preface to his novel *Adolphe* (1816), Constant wrote that 'all things are connected in nature' and suggested a link between 'religious belief' and 'enthusiasm for liberty'. Behind his lifelong work on the history of world religions, represented by *De la Religion considérée dans sa source, ses formes et ses développements (Religion Considered in its Source, its Forms and its Development)* (1824-31) and *Du Polythéisme romain (Roman Polytheism)* (1833), lay Constant's conviction that two related needs were fundamental to human beings: the need for freedom and the need to believe. For Constant 'le sentiment religieux' was not the illusion excoriated by D'Holbach, Helvétius and other Enlightenment philosophers (see Enlightenment, Continental). It was a real and permanent facet of human nature. Societies had evolved through the stages of theocracy, slavery, feudalism, absolute monarchy to rule by a privileged aristocracy; and at each stage the permanent human longing for freedom had brought resistance to oppression and the casting aside of outworn forms of government. Similarly, men and women of all historical periods had in them a religious sense or feeling, an inner need to rise above mere egoism that expressed itself in self-sacrifice and self-denial. All cultures had seen a constant struggle between the religious feeling of individuals, which was a living thing and needed to evolve and change, and the static outward shape imposed on it by a priestly caste in terms of forms of worship and dogma.

The parallel is clear: as an optimist and believer in human perfectibility, Constant believes that there is a law of movement in history in both in politics and religion that cannot be resisted. The need for liberty inherent in human nature will always ensure that those forms of government or of religious belief which are fixed, stagnant and unchanging are replaced by forms better adapted to the needs of the historical moment. In 'De la Perfectibilité de l'espèce humaine' (On the Perfectibility of the Human Race) (1829), it is unlimited human perfectibility that gives meaning to life - and indeed a form of survival beyond death in the progressive development of intellectual and spiritual qualities from generation to generation. Religious feeling had developed through history from primitive polytheism through theism to Christianity and had reached its highest form in modern Protestantism -

open-minded, tolerant and pluralistic. Yet every form of belief, like every form of government, was a provisional one and would ultimately be outgrown. Political wisdom required an eventual change in institutions to reflect the evolution of society (the ultimate goal being a society that allowed the greatest personal freedom), and likewise a tolerant state would enable religious feeling to be expressed in a form appropriate to a new age.

Constitutionalism

Constitutionalism comprises a set of ideas, principles and rules, all of which deal with the question of how to develop a political system which excludes as far as possible the chance of arbitrary rule. While according to one of the classic sources of constitutionalism, article sixteen of the 1789 French Declaration of the Rights of Man and of the Citizen, 'any society in which rights are not guaranteed, or in which the separation of powers is not defined, has no constitution', the scope of constitutional principles is in fact broader. In addition to these two defining principles, the following are essential: popular sovereignty; the rule of law; rules about the selection of powerholders and about their accountability to the ruled; and principles about the making, unmaking, revision, interpretation and enforcement of a constitution. Despite close affiliations, constitutionalism and democracy are not the same. Whereas democracy is an institutional device which realizes the right of the people to govern themselves, constitutionalism aims to establish institutional restraints on the power of the rulers, even if they are popularly elected and legitimized. Constitutionalism embodies the self-rationalizing and self-restraining principles of popular government.

1 The concept, its historical roots and main variants

Constitutionalism in the modern sense of the term embodies the philosophical and juridical response to man's quest for political freedom. It encompasses the values, principles, reasoning, institutional devices and procedures which shape the idea of an institutional framework by which political freedom is secured. This framework is called constitutional government, and the instrument by which it is established is the constitution. The components which make up constitutional government vary considerably in different countries, to the point that what is regarded as a core element of constitutionalism in one country is considered incompatible with constitutionalism in another. However, there are a small number of properties that over a long period have been taken to define the very essence of constitutionalism, and about which there is a broad consensus.

The following precepts are basic to modern constitutionalism. First, the claim that the arbitrary will of the political ruler(s) must be submitted to rules. A government under law, a rule that governs the governors or, in the most pointed version, the rule of law and not of men, are but different ways of expressing the essence of modern constitutionalism. The term 'rule' means 'legal rule'; however, in particular cases extra-legal (political, moral) rules may also acquire constitutional quality if they are accepted as binding by both the ruled and the rulers (see Rule of law (Rechtsstaat) §1). Second, constitutionalism implies the principle of popular sovereignty. Although in nineteenth-century Germany the 'graciously granted' rules whereby sovereign princes affirmed certain limitations on their sovereign power were called constitutions, the concept of constitutionalism requires the constituent, or constitution-making power of the people. This follows from the premise that in modern societies the 'people' is the ultimate source of sovereign power; since constitutions shape the sovereign power, they can only be ordained by the sovereign (see Sovereignty). The third essential element of constitutionalism is the idea of limited government. This means that both the purposes of government, and the instruments available to power-holders to realize those purposes, are delineated - something implicit in the term 'constituted power'. This entails, as the most important institutional consequence for the form constitutional government is to take, some kind of separation of powers. Furthermore, constitutional government calls for rules which define the accountability of the rulers to the citizenry. Finally, constitutionalism requires that changes to the constitutional rules must be effected according to the rules of the constitution itself. Based on these minimum requirements, constitutional documents normally extend over three main issues: individual rights; the structure of government; and rules about the revision of the constitution.

These characteristics distinguish modern from ancient and medieval constitutionalism, neither of which knew the concept of sovereign power or that of the natural freedom of the individual. The demise of ecclesiastical power, and the resulting disruption of the balance between secular and ecclesiastical authority characteristic of medieval society, gave birth to the idea of supreme power originating from a single sovereign source, paralleled by the idea of natural, equally unlimited, individual freedom. As a new political structure based on the monistic character of power was created, the word 'constitution' was progressively used to counteract the unlimited power of the sovereign prince. Gradually it became associated with the concept of political freedom. Originally appearing in English political discourse at the beginning of the seventeenth century, and signifying the empirical state of the body politic by analogy with the human body, 'constitution' had acquired its modern and narrower meaning by the

end of that century. The term no longer referred to the social structure of a particular country, but to its government as formed by the law of the land. The locus of power and the domestication of power through law became the main point of interest. Moreover, during the seventeenth century, the age when the modern absolutist territorial state was consolidated, it became common to use the word 'constitution' in the sense of an eternal and supreme law.

Constitutional government has turned out to be the only viable alternative to either despotism or anarchy, the two main threats to political freedom. This was essentially Montesquieu's perception that among all states England was the only nation 'whose constitution has political liberty for its direct purpose'. This statement referred to the final triumph of constitutionalism in England's Glorious Revolution of 1688 which imported the three elements characteristic of what has become known as the Westminster model of constitutionalism; namely, parliamentary sovereignty; the rule of law; and the operation of so-called constitutional conventions. The latter element refers to legally non-binding political and moral conventions which ensure that the conduct of parliament (which by virtue of its very supremacy cannot be subject to laws) conforms to the sovereignty of the people, namely, to the will of the majority of the electors (see Montesquieu, C. §3).

Although England is undoubtedly the homeland of modern constitutionalism, since the last quarter of the eighteenth century its notion of constitutionalism and particular form of constitutional government no longer embody the definitive model. In its US colonies the English model became itself the object of a constitutional revolution: the Constitution of the United States was drawn up in 1787, and became effective in 1789, the first year of the French Revolution. Quite different understandings of constitutional government came to prevail in the USA and France, greatly expanding the idea of constitutionalism. While the essentials - the submission of political rule to rules, popular sovereignty, limited government and the accountability of the rulers to the ruled - remained untouched, the ensuing institutions stood in clear, even hostile, opposition to those of the Westminster model. The Americans, who felt that the English version of constitutionalism did not protect them against the arbitrariness of parliament, reinvented, although with a quite different meaning, the medieval distinction between constitution and ordinary laws, a move inconsistent with the notion of parliamentary sovereignty. From this they drew three ideas. First, the constitution is superior to government and ordinary law, hence it creates, defines and limits government, including the legislature itself. Placing the constitution at the top of a legal hierarchy entails, second, that the constitution as the ultimate source of authority of political power be fixed, ordained in an act of extraordinary legislation and written in a document. This in turn generated a third element, namely the precept that the superiority of the constitution over ordinary laws includes the authority of the courts to invalidate laws incompatible with the constitution ('judicial review'). One of the most significant implications of this is the protection of constitutional rights not just against the executive, but against the legislature as well.

In its turn, the French Revolution, in which the US notion of the constitution as a written document enacted by a constituent power and superior to ordinary laws was adopted, gave birth to a notion of rights which stood in stark contrast to the English notion. The latter is based on the inseparable connection between a right and the institutional remedies against its violation so that, in the words of Dicey, 'in England the law of the constitution is little else than a generalisation of rights which the Courts secure to individuals' ([1915] 1982: 119). The French model, in contrast, proclaimed the rights of the individuals as being assured by, and hence dependent upon, the constitution, so that the whole burden of guaranteeing rights was placed on the constitution.

This notion of rights is part of a more comprehensive set of ideas which the French Revolution has contributed to the conceptual development of constitutionalism. Its main characteristic is the understanding of the constitution as the written embodiment of universally valid principles and doctrinal truths which render it a kind of rational plan for an utterly rational and smoothly functioning polity. This constitutional standard of complete rationality entails an incessant quest for the perfection of the polity and has inserted a spirit of political dynamism into the concept of constitutionalism which is lacking in both the English and the US versions. Consequently, in the French variant legal mechanisms to enforce the constitution are less important than political means. Thus what seems paradoxical at first glance, namely that the truly revolutionary and philosophically extremely influential Declaration of the Rights of Man and of the Citizen of 1789 has played only a minor role in the constitutional life of France, is quite understandable. Constitutional rights embody political claims and are primarily satisfied in the sphere of politics. Likewise, French constitutions have never allowed judicial review. They have mostly relied instead on the operation of the political process in general and parliament in particular to enforce the constitution. On the other

hand, the French constitutional model's responsiveness to the political process has facilitated the incorporation of substantive policy goals (like social rights or state goals) in the constitution. Such a purposive constitutionalism is alien to US constitutional reasoning, which views it as a potential risk to the legal normativity of the constitution. Moreover, given the origin of US constitutionalism, Americans trust the courts more than parliaments.

2 Problems, tensions and difficulties

Since the basic idea of constitutionalism is essentially the substitution of reason and rule for the arbitrary will of man, a pivotal element of constitutionalism is the conceptual clarification of the binding force of constitutional rules. If the concept of popular sovereignty includes the supreme power of the people to establish whatever political order it pleases, and if at the same time constitutionalism embodies the idea of forming, and hence restraining, sovereign power, do these not represent inconsistent principles? Moreover, is not the term 'constitutional democracy' an oxymoron? Traditional answers to these questions affirm that indeed there is a tension between constitutionalism and democracy, but they regard constitutional government as a justifiable restraint on democratic rule in order to protect minorities against the will of the majority (see Democracy §3). More recent analyses of constitutionalism emphasize the dialectics of self-binding and point to the fact that constitutions are not only devices against majorities, but serve equally to protect majorities themselves from myopia, moral weakness and a lack of self-restraint. In this understanding both democracy and constitutionalism share the goal of limiting the risks of political liberty and of politics generally, but employ different means: the former protects the individual right to an equal share in the political process, the latter 'lowers the stakes of politics' by enabling the sovereign to exercise governmental self-restraint through institutional devices (Murphy 1993). On this view constitutions are not primarily disabling devices; rather, they serve as a support for democratic self-government in that they enable the people to preserve the conditions of political freedom and democracy, better to recognize the options open to democratic choice, to reduce the risk of irreversible mistakes, to develop the capacity for self-correction and to enhance their democratic capabilities through learning.

There is abundant evidence that the strategy of self-binding need not weaken an agent's capacity but frequently increases their options. The prime example is Ulysses, who had himself bound to the mast in order to be able to listen to the sirens without losing his life. Another instance is the prohibition of contracts to sell oneself into slavery: this does not restrict, but promotes, freedom. Having the collapse of the Weimar constitution in mind, the drafters of the German Basic Law wanted to shield the German people from the temptation of once again embracing totalitarian rule, and thus definitively excluded the option of abolishing basic constitutional institutions through any kind of constitutional amendment. Likewise, the prohibition to print money imposed on the states in article 1, section 10, paragraph 1 of the US constitution can be understood as a mechanism of self-binding against the temptation to pursue policies which induce inflation (Holmes 1988).

3 Future developments

The main political impulse which has given constitutionalism worldwide recognition as the concept of a well-ordered polity has been the desire to 'tame the Leviathan' which was born in the religious struggles of the sixteenth and seventeenth centuries. Despite the manifold refinements which it has undergone, and notwithstanding a growing awareness of the aforementioned enabling functions of constitutions, constitutionalism is still widely associated with the purely negative functions of limited government. It is therefore often wrongly conflated with liberalism. This view does not take sufficiently into account that constitutions, although rarely containing solutions to particular substantive policy problems, can be credited with having resolved difficulties besides those that result from arbitrary state power. Thus, for example, the modern welfare state is the result of amalgamating the working-class demand for social justice with the idea of citizenship, which is a pivotal element of constitutionalism (see Citizenship §§1-2). Likewise, the inherent learning potential of constitutional devices has allowed constitutional states to cope more successfully with the challenges posed by the destabilizing technological, economic, social and cultural changes since the middle of the twentieth century than political systems which for one reason or another lacked constitutional arrangements.

However, approaching the end of the twentieth century, modern societies suffer from difficulties for which the traditional concept of constitutionalism has no answer. Economic inefficiency, civic apathy, a lack of concern for future generations, the seemingly irresistible decay of educational institutions and the continual worldwide impoverishment of urban life are just a few examples of phenomena which until now have hardly been touched

upon by constitutional reasoning, even though they are of utmost importance for the quality of a polity. These problems facing a modern polity, which go beyond the traditional goal of preventing the arbitrary exercise of political power increasingly have been addressed by a school of thought which invokes the idea of a ‘new constitutionalism’. This is characterized by concern for a good polity and hence completely revokes the basic assumption of traditional constitutionalism; namely, that for the sake of civil peace any striving after the common good and common values had to be excluded altogether from the realm of politics. Paradoxically, with this the ‘new constitutionalism’ returns to the Aristotelian point of departure in reasoning about constitutionalism; namely, to the idea of the *politeia* (see Aristotle §§27-28).

Constructivism

Originally proposed by sociologists of science, constructivism or social constructivism is a view about the nature of scientific knowledge held by many philosophers of science. Constructivists maintain that scientific knowledge is made by scientists and not determined by the world. This makes constructivists antirealists. Constructivism here should not be confused with constructivism in mathematics or logic, although there are some similarities. Constructivism is more aptly compared with Berkeley's idealism.

Most constructivist research involves empirical study of a historical or a contemporary episode in science, with the aim of learning how scientists experiment and theorize. Constructivists try not to bias their case studies with presuppositions about how scientific research is directed. Thus their approach contrasts with approaches in philosophy of science that assume scientists are guided by a particular method. From their case studies, constructivists have concluded that scientific practice is not guided by any one set of methods. Thus constructivism is relativist or antirationalist.

There are two familiar (and related) criticisms of constructivism. First, since constructivists are self-avowed relativists, some philosophers argue that constructivism fails for the same reasons that relativism fails. But many philosophers of science note that relativism can be characterized in various ways and that versions of relativism can be useful in the interpretation of science. Therefore, constructivism's relativism does not by itself render it unacceptable. Second, constructivists are accused of believing that scientists literally 'make the world', in the way some make houses or cars. This is probably not the best way to understand constructivism. Rather, constructivism requires only the weaker thesis that scientific knowledge is 'produced' primarily by scientists and only to a lesser extent determined by fixed structures in the world. This interprets constructivism as a thesis about our access to the world via scientific representations. For example, constructivists claim that the way we represent the structure of DNA is a result of many interrelated scientific practices and is not dictated by some ultimate underlying structure of reality. Constructivist research provides important tools for epistemologists specializing in the study of scientific knowledge.

1 Constructivism and social constructivism

The term 'constructivism' refers to a cluster of related approaches to the study of science. All these approaches involve empirical studies of science emphasizing the social nature of scientific practice. Some constructivists draw the following theoretical conclusion from their empirical studies of science: namely, the truth or falsehood of scientific beliefs derives not from their relation to the world but from the social arrangements of scientists. Social constructivists maintain that social interests or factors in the micro-structure of scientific practice determine which beliefs are held to be true or false. Social constructivist case studies often focus on scientific controversies where resolution does not appear to depend on hard evidence or data, but on 'other factors'. Thus the claim that scientific knowledge is socially constituted results from the generalization of these other factors. This view is similar to a social-determinist view about belief formation. It is best exemplified by the Edinburgh School sociologists of science (see Bloor 1992) and Harry Collins' empirical programme of relativism (Collins and Pinch1993). Another constructivist view is that scientific facts are constituted by arrangements of scientists, and animate and inanimate objects. This view challenges social determinism on the grounds that society is no better understood than nature, and so claiming that to understand the study of nature one needs to understand society is premature. This view is shared by actor-network theorists such as Bruno Latour (1987), and reflexivists such as Steve Woolgar (1988) (see also Latour and Woolgar 1986). They develop the view in different ways, though we will refer to them both as constructivist.

Actor-network theorists, such as Latour, maintain that scientific knowledge results from the establishment of connections between objects, animals and humans. For example, our knowledge of the structure of DNA connects together several different scientific practices, instruments and techniques. Challenging the structure of DNA involves challenging an established set of connections between these domains. Since constructivist case studies aim to show how scientific activity leads to this connectivity, often the case studies have a historical dimension, starting at the time before a particular scientific fact was established.

The terms 'fact' and 'belief' are often conflated in constructivist literature, leading to some confusion. To avoid

further confusion we will define these terms as they are used here. Beliefs are propositions or sentences that are candidates for truth or falsehood. Individual scientists have various beliefs about their world. Facts are established pieces of scientific knowledge, as found in scientific textbooks. Though not the standard philosophical definition of 'fact', this definition will help in understanding constructivism.

Constructivism as discussed here is distinct from constructivism in mathematics or logic (see Constructivism in mathematics), and distinct from constructive empiricism in the philosophy of science. Constructivism shares antirealism with both these views and a kind of empiricism with the latter view. The antirealism in constructivism is expressed in the claim that the truth and falsity of scientific beliefs can be established independently of any evidence from the real world (Collins and Pinch 1993) (see Scientific realism and antirealism §4). The empiricism in constructivism is a methodological tenet: all studies of science should be empirical studies of scientific practice. Versions of constructivism, for example the reflexivist view, are more readily compared to some kinds of scepticism or idealism. These forms of constructivism, claiming that scientists have access to nothing other than representations, are reminiscent of the idealism of Berkeley (Woolgar 1988).

Constructivism is antirealist and relativist: constructivists reject the view that science discovers a determinate structure to reality and they reject the view that scientific knowledge is achieved by following one particular rational method. According to critics, the rejection of these views constitutes a fatal flaw in constructivism. Nonetheless most constructivists enthusiastically embrace the antirealist and relativist consequences of their position.

2 The development of constructivism

Constructivism has a long heritage in philosophy. However, its modern history consists of refinements to the view developed by the Edinburgh School in the sociology of knowledge.

The roots of constructivism are in the sociology of knowledge which can be traced as far back as Plato, who proposed a relationship between a citizen's knowledge and their place in society. Marx provided the starting point for modern sociology of knowledge when he claimed that ' it is not men's consciousness which determines their existence, but on the contrary their social existence which determines their consciousness' (Marx and Engels 1970: 51). Hence, to explain the genesis of human ideas Marx looked to social structures (see Marxist philosophy of science). The discipline addresses issues such as: what is the relationship between a society or social structure and what is known? Does society affect science or the knowledge of nature more or less than it does the knowledge of culture? What kinds of social force produce knowledge and what kind of analysis of society reveals these social forces?

The Edinburgh School of sociologists of scientific knowledge (Bloor 1992) are direct descendants of Marx. Bloor starts out from a critique of the Marxist sociologist of knowledge, Mannheim, who maintained that all knowledge, except for that generated by the physical sciences and mathematics, is socially determined. Bloor expands the sociology of knowledge to include the study of mathematics and scientific knowledge.

As well as responding to Mannheim, Edinburgh School constructivists are reacting to two other strands of thought. The first is American sociology of science, represented by Robert Merton (Merton 1973). Although Merton argues that the rise of science and its success results from social forces, he stops short of claiming any relation between the content of scientific knowledge and society at large. Merton studies science as an institution within society, divided up in particular ways. There are reward systems and hierarchies designed to maintain its social order in accordance with certain norms. Merton is sympathetic towards a logical empiricist account of the status of scientific knowledge. He agrees that philosophical analysis can uncover the method by which scientists achieve knowledge. The Edinburgh School maintains, contra Merton, that scientific knowledge can be examined sociologically.

Edinburgh School sociologists react to a second strand of thought that they call 'traditional philosophy of science'. They reject any philosophical approach that explains the attainment of scientific knowledge in terms of a method or set of methods. They also reject any approach that proposes only one standard of rationality. In Edinburgh School literature 'traditional philosophy of science' includes logical positivism, logical empiricism, Popper, Lakatos and Laudan (see Logical positivism; Scientific method). Further, Edinburgh School sociologists claim that traditional philosophers of science ignore empirical information about scientific practice in their

studies.

The Edinburgh School defends a view known as ‘interest theory’ in the sociology of scientific knowledge. This view can be understood as a set of methodological directives for the study of science. Since they argue that the truth or falsehood of scientists’ beliefs are determined by social interests, they explain the validation of all scientific beliefs using the same causal model. Empirical studies of science are therefore undertaken to establish the derivation of particular scientific beliefs. The results of these studies lead them to conclude that scientific beliefs are not made true by any rational method that aided in their acquisition. Philosophers of science are often confused by the presentation of this position as the Edinburgh School deliberately conflates a method for explaining how they arise and a method for explaining how these beliefs are validated. This is a troublesome conflation, if one takes seriously the distinction between justification and discovery. But in fact, the Edinburgh School attacks this distinction explicitly; the conflation is an important tactical move. It is difficult to decide, however, what a causal explanation of belief validation amounts to (Roth 1994).

Finally, the Edinburgh School argues reflexively that the methodological directives should be applicable to the studies of science that result. In other words, any knowledge obtained about science can be explained by the interest model. In their view such reflexivity ensures that the social study of science is as scientific as the natural science under scrutiny (Bloor 1992).

What all constructivists accept from the Edinburgh School’s account is a method, or loose set of directives, for how to study science. Minimally they accept the injunction to study science empirically as it is practised on a day to day basis. The historical version of this method - which is to move away from a study of scientific texts to the social context the texts arose from - also reveals that science is a messy business, a far cry from the linear and tidy affair implied by rationalist reconstruction.

Despite accepting the methodological directives, other constructivists try to avoid some of the more obviously problematic claims of the Edinburgh School. The Edinburgh School focused on beliefs as the unit of analysis, arguing that scientists’ beliefs are determined by their social interests. Constructivists such as Latour and Woolgar (1986) concentrate more on ‘scientific facts’. This changes the focus of study from knowledge as the possession of individuals to knowledge as a commodity or shared object. This approach introduces a more materialist view of knowledge. An example may help illustrate this point.

A scientific fact is represented in any key content statement from a scientific textbook. For example, a popular neuroscience textbook points out that dopamine-beta-hydroxilase is only present in terminal buttons of nerve cells producing nor-epinepherin. This statement is established in neurobiology and has a key place in research. Latour (1987) refers to such facts as ‘black boxes’: once in place they are never challenged or re-investigated. Fifty years ago the textbook statement would have made no sense, because there was no application for its use. The statement was a conjecture even half-way through the testing of the difference between nor-epinepherin terminal buttons and dopamine terminal buttons. Later it becomes a strong hypothesis, and, finally, is accepted by all researchers in the field.

What constructivists investigate is the ‘hardening’ of such facts, the transformation of conjecture into established background knowledge in a field. Constructivism is the view that such facts are not revealed to scientists, but are constructed by them. But this construction of scientific facts is not merely a social process. Constructivists, such as Latour (1987), challenge the Edinburgh School social-determinist assumption that scientific knowledge is determined solely by social factors, arguing that: the social determinist thesis fails because we do not understand society any better than we do the natural world. For social factors to be a suitable candidate for the sole explananda of scientific knowledge we require a well-developed understanding of society. These constructivists claim, however, that by studying science as the connecting point between society and nature, we improve both our understanding of society and scientific knowledge.

From their empirical discoveries about that nature of scientific practice, constructivists go on to make general claims about science. Importantly, they claim that scientific knowledge is constructed by scientists, not discovered (Woolgar 1988). Constructivists get into difficulty cashing out this claim. Several philosophers criticize careless presentations of constructivism, which imply that scientists literally make the world by negotiating among themselves. What is important about constructivism is the emphasis on the construction of scientific knowledge:

constructivists do not emphasise the construction of the world, but the construction and acceptance of representations of the world.

3 Criticisms and replies

Critics of constructivism charge that the view is necessarily relativist. Next they conclude that since relativism is *prima facie* unsatisfactory, so is constructivism. Can this charge of relativism be answered? Though constructivists have not answered all charges of relativism, they have suggested ways around some of its forms. In what follows we will first survey the many kinds of relativism and then discuss constructivists'responses to this kind of criticism (see Relativism; Epistemic relativism).

Philosophers of science have presented relativism as a menace to science, knowledge, rationality and just about everything else. For example, Larry Laudan says:

> The displacement of the idea that facts and evidence matter by the idea that everything boils down to subjective interests and perspectives is - second only to American political campaigns - the most prominent and pernicious manifestation of anti-intellectualism in our time.
>
> (Laudan 1990: x)

In contrast, many sociologists of science cheerfully embrace relativism. Let us look at some of the forms of relativism that constructivists embrace, before critically assessing them.

Relativists are reacting to two main types of opponent: the realist and the rationalist. We can thus distinguish two broad categories of relativism: antirealism and antirationalism. Laudan characterizes relativism with respect to scientific knowledge as ‘ the thesis that the natural world and such evidence as we have about that world do little or nothing to constrain our beliefs’ (1990: viii). He adds that the relativist slogan is ‘ the way we take things to be is quite independent of the way things are’ (1990: viii). This is antirealist relativism. The negative thesis of antirealism can be formulated as several different positive theses, versions of which are common in the literature. For example:

(a) Scientific knowledge is produced by the whim and fancy of indiviual scientists.
(b) Scientific knowledge is determined by social arrangements of the community of scientists.
(c) Scientific knowledge is determined by the wider political and social interests of individual scientists.

The realist here would argue that scientific knowledge is in some way determined by the real nature of the world. A weaker version of this claim is that knowledge is constrained by the nature of the world.

Another criticism of relativism is that scientific knowledge is further determined by scientists following particular rational methods. This is a thesis about the rationality of scientists and is independent of the realist criticism. The rationalist thesis is opposed by antirationalist relativists who insist that there is no one set of methods guiding scientists to the truth. Critics claim that antirationalism entails that no one set of knowledge claims has any special claim to validity over any others. But this latter position involves an extra step of reasoning and should be distinguished from antirationalist relativism: it can be called judgmental relativism (Knorr-Cetina and Mulkay 1982).

One final distinction is worth making: relativism is not equivalent to subjectivism, although subjectivism is a kind of relativism. A subjectivist believes that the truth of a scientific statement is decided by an individual scientist. Those who hold thesis (a) above are subjectivist and relativist. But there are those who believe that establishing the truth or falsehood of a claim has little to do with individual whim, and yet still has nothing to do with the real world or the scientific method. Those who hold thesis (b) above are in this position. Only thesis (a) above is subjectivist.

Constructivism is not wedded to either subjectivism or judgmental relativism. The assumption that all forms of relativism collapse into one or other of these positions is mistaken. An example of judgmental relativism about scientific knowledge is the claim that it is no more valid than a collection of beliefs about witches. Constructivists will join anyone else in acknowledging that, as a result of advances in scientific knowledge, diseases can be held at bay, we speak to each other across continents and fly around the world. Meanwhile belief in witches' remedies and broomstick travel simply have not caught on throughout society. Constructivists want to answer questions about

why science is more successful than ‘witchcraft’, and so judgmental relativism is not a fruitful theoretical tenet for them. Subjectivism is no more promising as a theoretical basis for addressing such questions.

Critics could still maintain that even if constructivism is not wedded to judgmental relativism or subjectivism, it is still relativist. Why would anyone attempting to give a coherent account of scientific knowledge production be relativist? Constructivists’ defences of relativism derive in part from methodological considerations about the study of scientific practice. Bloor’s symmetry principle (1992) is motivated by these kinds of consideration. The principle states that the causes of a scientific belief can be of the same kind irrespective of that belief’s later acknowledged truth or falsehood. False beliefs, according to Bloor, are not caused by special irrational means. The results of studies guided by this methodological assumption lead Bloor and others to conclude that impartial empirical studies of scientific practice do not lead to rationalism or realism about science. (Paul Feyerabend endorsed similar kinds of conclusion in his historical studies.) This kind of argument amounts to an issue of the burden of proof. Some constructivists, however, reject this argument, resorting to the higher level claim that distinctions between relativism and rationalism or relativism and realism are simply the products of a form of analysis. They suggest that, with a shift of emphasis in the study of science, such distinctions will be rendered obsolete. Latour (1987) adopts this approach.

Latour argues that scientists make claims credible by placing them in a network of objects, other scientists, instruments and other knowledge claims. The following illustrative contrast illuminates this point. There are no widely available textbooks on broom travel, few flying brooms have been seen supporting human weight, and no brooms have challenged aeroplanes as vehicles of commercial air travel. By way of contrast aeroplane travel enjoys much support. In challenging the viability of airplane travel, however, we realize how physically and socially entrenched it is: there are textbooks on fluid dynamics and jet propulsion, and flight schedules are kept daily. Though few scientific facts are as indubitable or widely believed as the fact that 747s fly, all scientific facts are connected to a set of instruments, practices, prominent scientists, observable effects and objects. Latour’s suggestion is that it is possible to tell a constructivist story about how some beliefs have more perseverance than others, without invoking philosopher’s traditional standards of rationality, by accounting for all the connections between the various objects, instruments and social intitutions that constitute the facts that the beliefs pertain to. Notice that on this account, contra antirealist relativism, objects do play a part in determining the validity of scientific beliefs. On this view scientific beliefs acquire authority from the role scientific facts play in connecting social and natural systems. Purported facts supporting other belief systems lack this authority.

This proposed way around relativism rids constructivism of an obviously self-destructive judgmental relativist or subjectivist component; but constructivism is still relativist. Certainly, scientific knowledge is validated by different methods in different fields, and was validated by different methods in earlier epochs; but uncovering these methods is part of the study of science. If this is relativism, then constructivism is relativist. But acquiescence to this kind of relativism is not a disaster.

Though constructivism may not suffer from a disastrous relativism, some argue the view is simply absurd (Devitt 1991). Constructivist sociologists often make an ontological claim that scientists construct objects, and this, according to many critics, is absurd. Of course, scientists do construct objects, thousands of them: telescopes, microscopes, oscilloscopes, micro-pipettes; and, on the smaller side, synthesized enzymes, proteins and chemicals of all kinds. Claiming this is surely not absurd; it is simply stating what goes on in scientific practice. Devitt and others worry that Latour and Woolgar’s (1986) claim that Guillemin and his team *made* Thyrotropin Releasing Factor (Hormone) implies they did not discover it. And Devitt quotes Latour and Woolgar generalizing this point, saying:

> Despite the fact that our scientists held the belief that the inscriptions could be representations or indicators of some entity with an independent existence ‘out there’, we have argued that such entities were construed solely through the use of these inscriptions …objects …are constituted through the artful creativity of scientists.
>
> (Devitt 1991: 256)

A defence against Devitt’s accusation can be made from Latour and Woolgar’s comments about their methodological strategy. They emphasize that their claims about making the world are part of a rhetorical strategy whose methodological point is to detach us from the simple, and predominantly accepted, picture that scientists simply divulge facts about the world that are out there pre-packaged and ready for the taking. But, Latour and

Woolgar's defence aside, many constructivists appear to make the ontological, and not methodological, claim that scientists make up the world (Woolgar 1988). This kind of idealism is not a productive approach to the study of science. Fortunately constructivism does not require this view and nor do constructivists' methodological and epistemological claims require a grounding in any form of idealism (Fine 1996).

Some constructivists tackle ontological questions head on and, rather than endorsing an idealist position, they view nature as a source of resistance to human action (Pickering 1994). The natural world, they argue, is ill-defined and scientific research is a kind of social action that characterizes the world's resistance with various kinds of representation. This view of the world as an as yet undifferentiated source of resistance is the closest constructivists come to a version of realism. It should be noted that critics such as Devitt would not regard this constructivist version of realism as realist.

4 Constructivism as an epistemological thesis

Constructivists claim that a detailed description of what goes into the consolidation of a scientific fact is epistemologically relevant. Scientists consolidate facts with a great deal of effort, moving from a hypothesis about a particular experimental effect to a fact that connects with accepted knowledge in the field. Their effort to consolidate the fact contributes to its authority. Describing how facts accumulate authority helps constructivists understand the distinctive nature of scientific knowledge. This is one version of a story familiar to naturalistic epistemologists (see Naturalized epistemology; Social epistemology). Understood in this way, constructivism is part epistemological and part methodological, and need make no ontological claims.

On the constructivist view, scientific facts acquire authority by passing through several kinds of legitimation strategy. One of the most important of these strategies is for a fact to guide all future practice in a particular area of research. One cannot investigate energy transfer in the mitochondrion without accepting the fact that there are mitochondria, and that they are the loci of energy transfer. Facts accumulate authority by attaching to experimental practice, constraining future experimental practice, being embodied in pieces of equipment, and being unquestioned by members of the scientific community. Constructivists claim to have established empirically that scientific facts do not gain their authority by satisfying standards of certainty or rationality for individual scientists.

Philosophers of science who share the view that empirical studies of scientific practice make an important contribution to understanding science may think that constructivists will contribute to epistemology (Nelson 1994). An epistemology suited to the practicalities of scientific practice has to account for all of science's particularity. Constructivism is most fruitfully interpreted as a contribution to naturalized philosophy of science and as joining in the attempt to give a naturalistic account of the attainment of scientific knowledge.

Constructivism in ethics

There have been many forms of the idea that there are no distinctively ethical properties, and that ethical claims are composed or constructed out of other considerations. In some sociological writing the term is used for the view that ethics is artificial or socially constructed, for example out of social norms or attitudes. However, constructivism in ethics is now identified mainly with certain views not of the source but of the justification of ethics, which have their origin in Kant's work and have been revived and developed by John Rawls. Constructivism in ethics seeks to show how substantive principles, and in particular principles of justice, can be built out of minimal, uncontroversial elements, such as a slender account of action and reason.

1 Social constructivism and constructivism in ethics

The idea that ethical ideas and institutions, like other ideas and institutions, are not basic features of the world but are *made* or *constructed* by human beings has a long history. Protagoras claimed that man is the measure of all things; Hobbes depicted the state and justice as a mortal God made by men; Hume argued that justice is an artificial virtue (see Protagoras §3; Hobbes, T. §§6-7; Hume, D. §4). The twentieth century has seen a wide range of claims that standards of right and wrong, good and bad are constructed. Most of these claims assert that actual ethical norms are the *social constructs* of particular human societies, without relevance or validity beyond the societies in which they arose. Their proponents speak of the social construction of reality (of meaning, of science), the construction of social identity, the construction of political attitudes - and the construction of ethics (see Constructivism). When ethical norms are viewed as social constructions the aim is to explain rather than to justify them; in general social constructivism has interested sociologists more than it has interested philosophers.

A more specific and philosophically significant view of the construction of ethics identifies it with the claim that ethical principles can be justified by appeal to elementary and uncontroversial features of action and reason. Constructivism in ethics can be contrasted both with forms of ethical realism and with many conventionalist or relativist views of ethics (see Moral realism; Moral relativism). Unlike realists, constructivists deny that there are any distinctively moral facts or properties, whether natural or non-natural, which can be *discovered* or *intuited* and which provide the foundations of ethics (see Fact/value distinction; Naturalism in ethics). Unlike conventionalists or relativists, constructivists think that it is possible to justify universal ethical principles (see Universalism in ethics). The distinctive feature of constructivism in ethics is the claim that universal ethical principles can be built out of quite minimal accounts of action and reason.

2 Kantian constructivism: Rawls

At first glance it might seem that most utilitarian and kindred ethical theories are constructivist, because they do not assume that there are objective moral facts and properties, and they aim to justify universally valid ethical claims (see Utilitarianism). However, the term 'constructivist' is not generally applied to utilitarian ethical theories, because their arguments appeal not only to conceptions of action and reason but to individual desires and preferences. It is usually reserved for positions which do not draw on assumptions about the content of desires and preferences in justifying ethical conclusions. For this reason constructivism in ethics is often spoken of as 'Kantian constructivism' (see Kantian ethics).

The leading exponent of Kantian forms of constructivism is John Rawls, who has developed a range of arguments for constructivist approaches to the justification of principles of justice. In *A Theory of Justice* (1971), he uses the term 'constructive' very broadly to refer to ethical positions, including utilitarianism and his own contractualism, which seek to provide procedures for resolving moral problems (see Contractarianism §§7-9). He contrasts constructive positions with theories, such as intuitionism, which provide only a plurality of unranked principles, hence no adequate procedures for resolving ethical problems (see Intuitionism in ethics).

In his later work, beginning with 'Kantian Constructivism in Moral Theory' (1980) and continuing through *Political Liberalism* (1993), Rawls uses the term 'constructivist' more narrowly to refer to methods of reasoning in ethics which not merely offer ways of justifying substantive principles, but do so on the basis of minimal and supposedly uncontroversial claims about reason and action, and without referring to agents' desires or preferences. In these later writings Rawls no longer views utilitarianism as a constructive position and argues only for a

constructive theory of the right, and so of justice. He also concludes that no constructive account of the good or of virtue can be given, and that we must accept that there is no rational way of choosing among conceptions of the good.

The most controversial features of Rawls' subtly differing versions of ethical constructivism are his considerations about the resources out of which an account of substantive ethical principles is to be constructed. His justificatory arguments assume that we can appeal not merely to instrumental but to other conceptions of reason or reasonableness. In *A Theory of Justice*, he had argued that principles of justice were justified if they were in *reflective equilibrium* with our considered moral judgments. In 'Kantian Constructivism in Moral Theory'(1980) he viewed persons as 'agents of construction' who appealed to certain ideals, such as a Kantian ideal of the person, in justifying principles of justice. In 'Justice as Fairness: Political not Metaphysical' (1985), he went on to argue that justifications could appeal to ideals which are constitutive of the identities of citizens of liberal societies. In *Political Liberalism* (1993: 49) he argued that 'persons are reasonable…when…they are ready to propose principles and standards as fair terms of cooperation and to abide by them willingly, given the assurance that others will likewise do so' and that this conception of 'public reason is characteristic of a democratic people: it is the reason of its citizens, of those sharing the status of equal citizenship' (1993: 213). Discussions of Rawls' versions of constructivism have questioned whether appeals to the ideals or identities of citizens, or to their conception of fair terms of cooperation, can count as forms of reasonableness.

3 Kantian constructivism: other possibilities

Several other recent writers have proposed alternative versions of ethical constructivism, and have argued that these can be used to justify universally valid ethical principles. Thomas Scanlon (1982) has proposed that moral principles are those which parties similarly motivated could have no reason to reject. Thomas Hill (1989) has suggested that Kant's 'Kingdom of Ends' can be seen as a constructive model for deliberating about moral principles. Onora O'Neill (1989, 1996) has proposed ways of reading Kant and of developing Kantian ethics that not only construct substantive ethical principles out of elementary conceptions of agency and reason, but construct an account of practical reason itself out of the necessary conditions for principles to be adoptable by all relevant parties, so explicating the Kantian identification of practical reason with universalizability.

Constructivism in mathematics

Constructivism is not a matter of principles: there are no specifically constructive mathematical axioms which all constructivists accept. Even so, it is traditional to view constructivists as insisting, in one way or another, that proofs of crucial existential theorems in mathematics respect constructive existence: that a crucial existential claim which is constructively admissible must afford means for constructing an instance of it which is also admissible. Allegiance to this idea often demands changes in conventional views about mathematical objects, operations and logic, and, hence, demands reworkings of ordinary mathematics along nonclassical lines. Constructive existence may be so interpreted as to require the abrogation of the law of the excluded middle and the adoption of nonstandard laws of constructive logic and mathematics in its place.

There has been great variation in the forms of constructivism, each form distinguished in its interpretation of constructive existence, in its approaches to mathematical ontology and constructive logic, and in the methods chosen to prove theorems, particularly, theorems of real analysis. In the twentieth century, Russian constructivism, new constructivism, Brouwerian intuitionism, finitism and predicativism have been the most influential forms of constructivism.

1 Orientation

A call for ‘constructive existence’, standardly thought a hallmark of constructivism in mathematics, represents a general, revisionary attitude towards certain crucial statements of existence. That attitude is expressible as E:

(E) A mathematical statement $\exists x M(x)$, if crucial, is admissible only if a well-defined *a* can be constructed such that $M(\mathbf{a})$ is admissible, where a denotes *a*.

For E to be revisionary, the constructivist must indicate which claims are to be crucial, provide accounts of well-definedness and constructibility, and respond to any disruptions in traditional logic incited by E. It is in terms of these requirements that the outlines of influential forms of constructivism are demarcated.

Well-definedness. E need not govern all existential statements. Forms of constructivism are earmarked by choices of crucial statements, statements to which E is to be applied. Predicativists impose a version of E on claims about classes, but sometimes ignore E in elementary number theory. Russian constructivists put all their mathematics under the aegis of a strict reading of E.

As a call for revision, E is nugatory without strictures on well-definedness and constructibility. Conventionally, whenever $\exists n A(n)$ holds of natural numbers, there is a determinate *m* which is the least number for which $A(x)$ holds. However $\exists n A(n)$ is proved, one might then think to ‘construct’ an *n* such that $A(\mathbf{n})$ by using the computable function which outputs the number *m* on any input. So, unless the constructivist supplies further explanation, any proof of $\exists n A(n)$ might seem to satisfy E.

In general, well-definedness is explained in terms of canonical notations. Some constructivists count a natural number canonically denoted once a tally-mark numeral is available for it. Constructivist E. Bishop identified well-defined integers with number descriptions which are convertible into base-ten numerals. A real number may be deemed well-defined once a finitary recipe for approximating it is at hand. A predicativist about classes refuses classes not admitting definition in suitably predicative terms.

If well-definedness depends upon supplies of notations, it is natural to imagine constructive mathematical realms as nominalistic in that everything in them be nameable. It is also common to picture constructive realms as expanding over time as more notations are created. Some see in this image a contemporary rendering of Aristotle’s notion of potential infinities, of domains which are inexhaustible not because there now exist infinitely many elements in them but because, over time, more elements always appear. Explicit treatment of time enters infrequently into constructive mathematics itself, Brouwer’s use of the creative subject affording a celebrated exception (see Intuitionism §3).

Constructions. Constructibility is explicated in functional or operational terms. In general, a value is constructible just in case there is a recipe for computing that value in principle. Again, definite restrictions are needed if E is to

fulfil a desire which often motivates constructivism: that acceptable definitions in mathematics lead to algorithmic computation. This desire is explicit in E *, a generalization of E many constructivists endorse.

(E *) The statement $\forall x \exists y A(x, y)$ is, if crucial, admissible only when there is a construction *o* which computes, given any well-defined value *a* for *x*, a well-defined $o(a)$ such that $A(\mathbf{a}, \mathbf{o}(\mathbf{a}))$ is admissible.

Conventionally, axioms of choice ensure that, when $\forall x \exists y A(x, y)$ holds, there is a function *f* such that $\forall x A(x, \mathbf{f}(x))$ holds too. Hence, talk of 'constructions' must amount to more than talk of conventional functions. Once again, forms of constructivism are differentiated in the kinds of construction allowed. Traditional intuitionists demand that the class of constructions include only those operations given by computing recipes which humans can, in principle, follow. Finitists seem to want more: that recipes be guaranteed to output on any admissible input. Given their nominalistic leanings, certain constructivists identify operations with explicit rules or linguistic expressions of rules.

Constructive logics. Constructivism almost always calls for radical revisions in conventional mathematics. E may require, of any statement, that its admissibility entail the availability of constructions. To see why, take a statement *S* and define a predicate $A(x)$ so that $A(x)$ is true of 0 alone, if *S* holds, and of 1 alone otherwise. Trivially, when *S* holds, there is an *m* such that $A(\mathbf{m})$ and, given E, there must be a construction of such an *m*. But there is more to see from this example. If the law of the excluded middle (LEM) is valid, there is a simple proof of $\exists n A(n)$. But, if the truth or falsity of *S* is unknown, this simple proof appears to violate E. Short of settling *S*, one cannot construct a well-defined *m* such that $A(\mathbf{m})$, if 'construction' and 'well-definedness' are interpreted restrictively, since such an *m* equals 0 just in case *S* is true. Therefore, E is so interpretable as to conflict with the validity of LEM.

It has also been said that constructivism requires changes in logic for the reason that mathematical claims, constructively treated, hold extra information in the form of recipes for construction. Supplying this information is a requirement on any constructively correct proof. Presumably, the proof of $\exists n A(n)$ just described does not bear appropriate information when *S* is unknown. In this regard, it is important to note that the impact of E upon logic should not be thought wholly restrictive. Constructive claims can feature in proofs not only as conclusions but also as premises and, hence, as yielding up extra information. Some constructivists, for example, read E * as underwriting logical principles for deducing, directly from $\forall x \exists y$ premises, axioms of choice.

One way constructivists delimit needed alterations to logic is by establishing canons for correct constructive proof. Given such canons, a principle of inference is to be allowed when it licenses inferences that preserve correct provability. Intuitionists and Russian constructivists, for example, require of disjunctive and universal claims that

(E $\vee$) a constructive proof of $(A \vee B)$ include an effective marker and a further constructive proof. If the marker has value 0, the further proof is one of *A* and, if the marker is 1, the proof is of *B* and
(E $\forall$) a constructive proof of $\forall n A(n)$ involve an operation *f* such that, for any number *m*, $f(m)$ yields a constructive proof of $A(\mathbf{m})$.

The basic idea of using canons of abstract proof to assess logical principles is apparent in the writings of Brouwer. A. Heyting and A.N. Kolmogorov were the first to devise both proof specifications for each form of mathematical statement and formal logics arguably correct with respect to them. (Kolmogorov's logic was not complete, however.) Allegiance to the logic of Heyting, if not to any particular formalization of it, is shared by many constructivists.

Logics obeying E $\vee$ and E $\forall$ may fail to certify LEM. To see this, let $A(n)$ be an undecidable predicate of natural numbers. Then, $\forall n(A(n) \vee \sim A(n))$ plausibly lacks a constructive proof. For, were there such a proof, it would yield a recipe *f* giving, computably in *n*, a marker $f(n)$ signalling, in each case, the truth or the falsity of $A(\mathbf{n})$ and contradicting the supposition that $A(\mathbf{n})$ be undecidable.

2 Russian constructivism

Prominent among Russian (or Markovian) constructivists have been A.A. Markov, who initiated the approach around 1950, N.A. Shanin and G.S. Ceitin. As constructivists, the Russians might be thought most exacting, since E is imposed on existential quantifications over any domain. Entities are well-defined only if they admit encoding

as natural numbers or as words on a finite alphabet. Encodings must be, as Markov wrote, ‘potentially realizable’ as concrete notation (1962: 2). Accordingly, Russian constructivists require operations to be given as Turing machines or Markov algorithms and, hence, as finite words. Sets are identified with arithmetic formulas with one free variable.

In virtue of their views on operations, a belief in (a version of) Church’s thesis (CT) is ascribed to Russian constructivists. CT’s most straightforward version is ‘Every total numerical function is Turing computable’. This CT is not, as in recursion theory, a hypothesis about the meaning of ‘informally computable’, but a powerful mathematical axiom. For example, CT entails, in Russian constructivism, the falsity of the general LEM. The Markovian implementation of E, then, enjoins upon Russian constructivists markedly anti-classical principles of logic and mathematics.

Unlike new constructivists and Brouwerian intuitionists, Russian constructivists adopt (a form of) Heyting’s logic as an official formal system. They employ an understanding of the system’s signs devised by Shanin on which the truth of an existential claim *S* records the existence of an algorithm on whose operation *S* is a specification. In the name of this understanding, mathematical principles including CT get adopted which are permitted by neither intuitionists nor new constructivists. Among these is Markov’s principle:

(MP) Whenever a natural number predicate $A(x)$ is decidable, $\exists n A(n)$ is provable constructively from $\sim\forall n{\sim}A(n)$.

When MP is rendered in algorithmic terms, a motive for adopting it is plainest. The decidability of $A(x)$ then requires a recipe *R* for determining membership in $\{n\colon\ A(n)\}$. If one runs *R* successively on inputs $0, 1, 2, \ldots$ searching for members of $\{n\colon\ A(n)\}$, a proof of $\sim\forall n{\sim}A(n)$ guarantees that this search cannot fail. MP says that, in these circumstances, there is an *m* such that $A(\mathbf{m})$ to which the search procedure will lead.

Adherence to CT lends Russian constructive analysis a computable cast throughout. As O. Aberth wrote, the mathematics ‘may be informally described as an analysis wherein a computation algorithm is required for every entity employed. The functions, the sequences, even the numbers of computable analysis are defined by means of algorithms. In this way definition and evaluation are made inseparable’ (1980: 2). There is no single conception of real number within Russian constructivism. A real is an ‘FR-number’, for example, when it is given in terms of a pair of algorithms, the first yielding a Cauchy sequence of rational approximants and the second a modulus of convergence. (‘FR’ stands for ‘fundamental sequence with regulator of convergence’.) The most famous mathematical theorem of Russian constructivism is that proved by Ceitin (and, independently, by Kreisel, Lacombe and Schoenfield), which implies that every function from the reals to the reals is continuous. In Russian constructivism, this does not entail, as it would conventionally, that every real-valued function on a closed interval is uniformly continuous. Using a result of E. Specker, Russian constructivists prove that there are continuous functions which are unbounded on closed intervals.

3 New constructivism

New constructivists (or Bishop constructivists) comprise a relatively small group of mathematicians inspired by E. Bishop. Bishop’s influential *Foundations of Constructive Analysis* banished lingering doubts that a significant mathematics could survive constructivization. It was consequent to the book’s 1967 publication that new constructivism had its greatest impact upon mathematics.

As for well-defined entities, new constructivists do not require that everything be coded as integers. In addition to numbers, they embrace abstract operations, functions (akin to extensional operations), proofs and sets. There is canonical number notation but no special notations for sets or operations. A set *S* is said to be ‘constructed’ once recipes are given for constructing *S*-elements and conditions are specified under which equalities between those elements can be proved. For example, a new constructivist real number is a triple $\langle r, p, s\rangle$ of operations *r* and *s* and a proof *p* wherein *r* is a sequence of rationals, *s* a sequence of natural numbers and *p* a proof that *s* is a modulus of convergence for *r*.

As far as constructions are concerned, only mathematical operations representable by demonstrably computable recipes are allowed. Even so, new constructivists refuse CT and set no a priori limit on the way recipes must be expressed. Nor do new constructivists endorse a particular formalism for constructive logic. Certain working

limitations are, however, discernible from a metamathematical viewpoint: CT has been proven consistent with systems reflecting Bishop's ideas. Metamathematical experience also suggests that all new constructive theorems are formally provable from suitable axioms via Heyting's logic.

Bishop insisted that new constructive mathematics capture the 'numerical meaning' of mathematical claims. Numerical meaning, he averred, is the sole clear and legitimate meaning for any mathematics. This meaning was to be cashed out in predicting the outcomes of performable computations on the integers, computations that come from realizing constructive theorems as computer programs. Bishop encouraged a comparison between formalizations of new constructivism and high-level specification and programming languages, ones whose proofs could be compiled into implementable code. This general idea of 'programming constructive mathematics' has since been taken up by a number of computer scientists.

The principal effort in new constructivism, which Bishop called 'the most urgent task of the constructivist' (1970: 54), is not a wholly autonomous construction of mathematics under the guidance of E but a painstaking *re*construction of classical mathematics intended to reveal its numerical meaning. The goal is to set as many traditional theorems as possible onto a constructive basis without offending conventional sensibilities. Conflict never erupts between theorems of new constructivism and those of conventional mathematics since new constructivists shun any anti-classical consequences of E.

Without benefit of nonclassical assumptions, new constructivists cannot prove, as their Russian colleagues do, that every real-valued function of a real variable is continuous. Moreover, Specker's theorem shows that they cannot expect to prove that continuous functions are bounded in range, even on closed unit intervals. In order to retain the boundedness theorem for continuous functions on such intervals, new constructivists supplement the traditional statement of the theorem with the extra hypothesis that the function is uniformly continuous. This kind of hypothesis supplementation has become a feature of all branches of new constructive mathematics.

4 Brouwerian intuitionism

The most celebrated of contemporary mathematical constructivisms, at least before 1967, was Brouwerian (Dutch or neo-) intuitionism. To an extent, the celebrity of intuitionism was allied to that of its leading exponent, L.E.J. Brouwer, who first presented the approach in articles appearing between 1907 and 1930 (see Intuitionism §§2-3). Brouwer and his followers maintained a relative liberality in the matter of well-definedness. Besides natural numbers, intuitionists granted full status to non-algorithmic or 'free choice' sequences, kinds of sets, abstract proofs (including infinitary ones) and moments of time. Brouwer refused nominalistic constraints: mathematical existence for him did not await the fashioning of notations. Mathematics was to be constructed as a free creation, unaided by realist metaphysics, linguistic representation or empirical data. Brouwer deemed an entity legitimate if it was apparent to a Neo-Kantian inner intuition. A well-defined entity could be displayed in intuition either as a mental construction from the perception of a passage in time or as a choice sequence or set of items so constructed.

From among a panoply of legitimate operations on numbers, intuitionists denominate as 'law-like' those functions which are computable by recipe. In keeping with his anti-linguistic bent, Brouwer did not establish strict limits on the means by which recipes are to be communicated and CT for law-like sequences is not intuitionistically acceptable. Brouwer expressed a concern (one which both Bishop and Markov later proved unfounded) that the law-like continuum - in which reals are identified with law-like sequences - would not support a satisfactory real analysis. This concern seems to have led him to import into intuitionistic mathematics an analogue of the probabilistic 'choice sequences' of Borel. For Brouwer, choice sequences need not be law-like or even fully determinate. There may be some restrictions set upon sequence terms to appear in future but, beyond that, nothing about the course of a sequence may be presumed known.

Traditionally, there are two intuitionistic analogues to the conventional notion of set: 'species' and 'spread'. Species are properties determined by extensional mathematical predicates and individuated extensionally: pairs of species are identical when they have the same members. Spreads, on which Brouwer laid great emphasis, are either species of choice sequences constrained to obey a 'spread law' or species of sequences obtained from those via continuous mappings. The generators of real numbers comprise a spread in the latter sense.

The quintessential intuitionistic result is 'Brouwer's theorem': every real-valued function of a real variable on a closed, bounded interval is uniformly continuous. Brouwer concluded from this that every real-valued function on

the reals is continuous. Brouwer's proof of the latter is markedly different from that which leads to Ceitin's theorem in Russian constructivism; it relies upon mathematical principles inconsistent with CT (see Intuitionism §3).

5 Finitism

As the name suggests, finitism requires that one eschew reference to infinite collections. In the case of Hilbert's finitism, this requirement was coupled with a desire, epistemically motivated, to replace abstract concepts with concrete, visualizable notation. Hilbert's idea was that a metamathematics confined to the realm of the visualizable would secure conventional mathematics against the paradoxes. Besides Hilbert's finitistic metamathematics, notable forms of twentieth-century finitism are represented by Skolem's primitive recursive arithmetic and Yessenin-Volpin's ultra-intuitionism.

For most finitists, only natural numbers or items encodable as natural numbers count as fully well-defined. Numbers are not conceived as constituting an infinite totality but as individually realizable in concrete notation. Hilbert would have had it that talk of natural number, finitistically construed, comes down to talk of (the intuitable forms of) strings of tally marks. He wrote, 'The subject matter of mathematics is, in accordance with this theory, the concrete symbols themselves whose structure is immediately clear and recognizable' ([1926] 1983: 142) (see Hilbert's programme and formalism).

If the use of unbounded existential quantification is believed to require infinite totalities, as it was by Hilbert, restriction E will be implemented finitistically using constructions carrying explicit bounds. Bounded existential quantifications over the natural numbers are usually finitistically admissible and other existentially quantified claims, when allowed, get treated as 'incomplete statements', abbreviations for bounded quantifications. Universal quantifications are, if admissible, finitistically reconstrued as free variable expressions each instance of which is verifiable or falsifiable by direct calculation.

Constructions do enter into finitistic mathematics, but not as members of an infinite domain of number operations, as in intuitionism. Nor are they identified with members of a category of abstract rules or infinite graphs. An operation on natural numbers is a finitistic construction if realizable as a combinatorial transformation of concrete signs for which explicit bounds on the number of steps required to complete the transformation have been given. Primitive recursive functions are natural candidates for finitistic constructions on the natural numbers since these functions are Turing computable functions definable without unbounded search routines. Whether the class of finitistically admissible functions includes more than the primitive recursive functions is a topic of disagreement.

In Hilbertian finitism, admissible statements are said to capture mathematical claims which are '*inhaltlich*' or contentual. Statements refusing finitistic reconstrual were considered not contentual but ideal, expressions lacking full content. For Skolem, only those statements whose truth-values are fully determinable via primitive recursive calculations are admitted. Arithmetical predicates which are composed of simple equations between primitive recursive terms combined by connectives and bounded quantifiers Skolem treated as primitive recursive functions. Therefore, systems representing this approach are called 'logic-free', since quantifiers and connective signs are not required. Because of the limitations on the kinds of claim permitted, the proofs in Skolem's and Hilbert's finitistic arithmetics obeyed conventional logic.

Finitistic number theory and analysis, in the style of Skolem, has undergone some development, notably by R. Goodstein. Various constructions of real number are examined, among them that of primitive recursive real number: a primitive recursive sequence armed with a primitive recursive modulus. Anti-classical mathematical axioms are refused; hence, there are no finitistic continuity theorems like Ceitin's. However, since finitistic mathematics is intuitionistically acceptable, neither will it be possible to contradict Brouwer's theorems. According to Goodstein, a finitist in the style of Skolem cannot prove that a bounded, monotone sequence of rational numbers is convergent.

The so-called 'ultra-intuitionism' of A.S. Yessenin-Volpin differs radically from the views just described. Standard concepts of natural number and Skolem's 'recursive mode of thought' are not accepted as unequivocally correct. Yessenin-Volpin limits well-definedness to numbers which are feasible rather than potentially realizable: to be well-defined, an ultra-intuitionistic number must be literally displayed as a notation. One might say that the well-defined numbers of ultra-intuitionism do not constitute a single potentially infinite series but form a tree, each

branch of which represents a temporally expanding series of tokens from some numeral system. From P. Bernays and G. Kreisel, commentators have adopted the term ‘strict finitism’ for application to such positions as Yessenin-Volpin’s in distinguishing them from more liberal finitistic conceptions. Among philosophers of language, the viability of strict finitism has proved a subject of controversy. M. Dummett (1975) has maintained that sorites-like paradoxes would so haunt strict finitism that it is revealed as incoherent; C. Wright (1982) has since raised serious questions about the correctness of Dummett’s conclusions.

6 Predicativism

Predicativism took impetus from the writings of Poincaré and Russell on the paradoxes and received influential, but troubled, expression in Whitehead and Russell’s *Principia Mathematica* (1910-13) (see Theory of types). Predicativistic approaches to the foundations of mathematics were later instigated or investigated by C. Chihara, S. Feferman, G. Kreisel, P. Lorenzen, H. Wang and H. Weyl, among others.

Predicativists would have it that all mathematical entities - or all higher-order entities - are logical classes and that their existence is governed by a version of E. A logical class $\{x\colon A(x)\}$ is predicatively well-defined on condition that all quantifiers in $A(x)$ are restricted to a range of classes or entities already known to be well-defined and including neither $\{x\colon A(x)\}$ nor any class presupposing it for its definition. Definitions $\{x\colon A(x)\}$ satisfying this condition are termed ‘predicative’ and others ‘impredicative’. Russell put forward the requirement that all classes be predicative in the form of what came to be known as the ‘vicious-circle principle’. According to Russell, predicative classes must be organized into types so that ‘any expression containing an apparent [bound] variable is of higher type than that variable’ ([1908] 1967: 182). Consequently, the favoured way to implement bans against impredicativity has been to devise hierarchical formal systems (predicative type theories) for class definition and manipulation.

An intended model of predicative formalism, greatly simplified, is segmented into an ascending sequence of orders or levels indexed by natural or ordinal numbers. At the lowest or 0 level is a collection of given elements such as the natural numbers. Level 1 contains those classes whose definitions involve quantifiers ranging only over the given elements, level 2 contains classes specifiable using quantifiers ranging either over the given elements or over classes of level 1, and so on. Each class has a level, so impredicative classes are ruled out. Formalisms embodying an idea of levels include the ‘ramified type theory’ of *Principia Mathematica* and Wang’s systems Σ.

A class is predicative thanks to a suitable definition or notation for it; that notation cannot be grasped before notations for classes of lower level are grasped. As Wang put it, ‘new objects are only to be introduced stage by stage without disturbing the arrangement of things already introduced or depending for determinedness on objects yet to be introduced at a later stage’ (1970: 640). Following Poincaré, one often imagines predicative universes as expanding over time.

As for constructions, we can think of each predicative class as the result of a well-founded construction process involving conventional logical or class operations such as complementation, intersection and union, and quantification which is predicatively restricted. Hence, the imposition of E upon predicative mathematics seems to call for no great alteration in the fundamental inferences of conventional higher-order logic, apart perhaps from variable indexing. Each variable may wear an ordinal index and quantifier rules be so restricted that bound variables share indices with substituted parameters.

Predicativism has not spawned a programme for reworking mathematics as influential as Brouwerian intuitionism or new constructivism. Even so, a wide variety of mathematical results are known. Weyl saw that the theorem that every non-empty bounded class of reals has a least upper bound is unobtainable in complete generality within (a restricted) predicative mathematics if reals get defined in terms of classes. He showed that, by treating reals as sequences, the theorem that every bounded, monotonically increasing sequence approaches a limit is predicatively provable, as are other theorems of analysis. Wang has argued that predicativists cannot retain Cantor’s theorem on the existence of uncountable sets.

Content: wide and narrow

A central problem in philosophy is to explain, in a way consistent with their causal efficacy, how mental states can represent states of affairs in the world. Consider, for example, that wanting water and thinking there is some in the tap can lead one to turn on the tap. The contents of these mental states pertain to things in the world (water and the tap), and yet it would seem that their causal efficacy should depend solely on their internal characteristics, not on their external relations. That is, a person could be in just those states and those states could play just the same psychological roles, even if there were no water or tap for them to refer to. However, certain arguments, based on some imaginative thought experiments, have persuaded many philosophers that thought contents do depend on external factors, both physical and social. A tempting solution to this dilemma has been to suppose that there are two kinds of content, wide and narrow. Wide content comprises the referential relations that mental states bear to things and their properties. Narrow content comprises the determinants of psychological role. Philosophers have debated whether both notions of content are viable and, if so, how they are connected.

1 Motivating the distinction

Many of our mental states, including our perceptions, memories and beliefs, represent things in the world and properties of those things (see Propositional attitudes). But this fact seems to produce a dilemma. On the one hand, representational states are what they are in virtue of how they represent things to be. That is, they are most appropriately individuated (distinguished from one another) by their different contents, which are comprised of things in the world (objects and their properties and relations; see Intentionality). On the other hand, in so far as these states play causal roles in our psychologies, they do so because of how the world seems to us, and presumably that is solely a matter of what is ‘in the head’. Their psychological roles would be just the same even if one were a brain in a vat or a victim of Descartes’ evil demon. The dilemma, then, is to reconcile the apparent facts that the representational character of mental states depends on their external relations and that their causal efficacy depends on their internal properties (see Methodological individualism). The distinction between wide and narrow content has been thought to resolve this dilemma.

Is this a genuine dilemma? Leaving aside such sceptical suggestions as that the contents of psychological states have no causal efficacy (see Mental causation), one might argue that the dilemma is illusory because, strictly speaking, contents *are* internal properties. Contrary to what many philosophers have supposed, the mere fact that the notion of content is connected with notions such as reference and truth-conditions does not mean that content is external. For this is compatible with a Fregean conception of content. Frege held that linguistic expressions have sense as well as reference, and the same might be suggested about concepts. Each concept expresses a condition of reference (a sense) and what it refers to is whatever satisfies that condition; and this condition is not dependent on external features of the thinker’s situation and is not otherwise sensitive to contextual factors (see Sense and reference). If concepts are Fregean in this way, then any two thinkers entertaining thoughts with the same conceptual composition are, regardless of their external circumstances, thinking thoughts with the same truth-conditions. This rules out the possibility that, because of sensitivity to circumstances, one could be thinking something true and the other, something false.

One difficulty with this Fregean view is its inability to handle thoughts that are about particular individuals. Thoughts such as ‘That’s a canary’ seem to be essentially indexical, in that their truth-conditions are relative to their contexts of occurrence (see Content, indexical): different people, having qualitatively identical experiences, could think thoughts of that form but be thinking of different birds.

A similar problem for the Fregean picture is posed by recognitional concepts: one might see a certain exotic insect and think, referring to its type, for which one might have no name, ‘That must be indigenous to the Amazon’. One might later observe a similar specimen and think, ‘It must be another one of those’, referring to the same type. One would be mistaken if, no matter how much the second looks like the first, it is actually an insect of a different type. Thus the property of being of the type initially picked out is not a matter of fitting a certain image or conception. Whether or not one’s concept of that type applies to the next specimen depends not on whether it fits one’s conception but on whether it is in fact a thing of the same sort as the one originally picked out. So it seems that the Fregean picture does not apply to recognitional concepts.

2 Twin earth thought experiments

A similar difficulty was revealed by Putnam's celebrated 'twin earth' thought experiments (1975), which introduced the distinction between wide and narrow content (see Putnam, H.). Twin earth is a place where everything is just like it is on earth, except as otherwise specified. In one scenario, two men, Art and Bart (Art's counterpart on twin earth), each have thoughts that they express with the words 'Water quenches thirst'. However, on twin earth the clear liquid that fills the seas and falls from the skies is composed not of H_2O but of some other stuff, XYZ. It is 1750 and Art and Bart, like everyone else, are ignorant of chemistry and could not, even if they had the opportunity, tell the difference between H_2O and XYZ. Nevertheless, Putnam contends, Art and Bart use the word 'water' to express different concepts. If Art were to classify a sample of XYZ as water, he would be wrong, for it would not be a substance of the same kind as water. As for Bart, he does not take XYZ to be water, for he does not have the concept 'water'. So Art and Bart, even though they are not different neurally, have different concepts, with different conditions of correct application. Their concepts are not determined solely by what is in their heads (see Concepts §5; Methodological individualism).

Burge (1979) conducts another thought experiment designed to show that differences in people's social environments can make for differences in mental content. An arthritic patient called Al complains, 'My arthritis has spread to my thigh'. Nothing in his acquisition of the term 'arthritis' has kept him from supposing that this inflammatory disease can occur in the bones as well as the joints. Meanwhile, Cal, his twin earth counterpart, registers a similar complaint. There, however, the term 'arthritis' is used to refer to an inflammatory disease of either the joints or the bones. Cal's exposure to the term 'arthritis' is the same as Al's, but, given how it is used on twin earth, he understands it correctly. Now, according to Burge, both patients are correctly said, on their respective planets, to believe that arthritis can occur in the bones, but, since Cal's belief is true and Al's is false, what they believe is different. However, there is no internal difference between them. Therefore, what they believe is partly an external matter. Contents are not, and do not supervene upon, what is in the head.

These thought experiments have met with considerable enthusiasm but also with neglected criticism (see Unger 1984; Bach 1987; Crane 1991). For one thing, they are conducted selectively: varying their details can yield contrary intuitions, for example, that XYZ is a kind of water. Also, even granting the correctness of the intuition, for example, that XYZ is not a kind of water, they leave it a mystery why the references of different concepts should be determined in different ways. The reference of the concept we express with 'water' depends on the nature (H_2O) of the clear, plentiful liquid around us, but this is not the situation with the concepts we express with the terms 'earth', 'air' and 'fire', whose references are chemically heterogeneous and are determined by the satisfaction of certain phenomenological conditions. Putnam and his followers do not explain why the fact that water is a chemical natural kind, and earth, air and fire are not, should make the concept water a different kind of concept from the concepts earth, air and fire, with its reference determined in a fundamentally different way, even back in 1750.

The arthritis argument depends essentially on the supposition that one can have beliefs with contents one 'incompletely understands'. It assumes, for example, that Al not only misunderstands the word 'arthritis' but operates with the concept arthritis rather than with some broader concept (call it 'tharthritis') that he mistakenly associates with the word. So, it might be objected, Al understands the term 'arthritis' in precisely the same way as Cal does, and has the very same belief, namely that his tharthritis has spread to his thigh. Whatever evidence there is that he also believes that his arthritis has spread to his thigh is overridden by his idiosyncratic understanding of the term 'arthritis' (we are not tempted to say that he believes that he has inflammation of the joints in his thigh).

In any case, we cannot assume that what 'that'-clauses capture is the sort of content relevant to psychology, that is, to characterizing people's perspectives and explaining their actions and inferences. As Loar (1988) and Patterson (1990) have both argued, one can grant that the thought experiments succeed in showing that the truth-conditions of attitude ascriptions are sensitive to aspects of the physical and social environment without granting that 'that'-clauses capture psychological content (see Propositional attitude statements). After all, semantics (of natural language) is not psychology.

3 Two kinds of content?

Burge is satisfied that there is only one kind of content, the externalist kind revealed by the thought experiments

and specified by 'that'-clauses in attitude ascriptions, and that no other kind is needed for psychology. Other philosophers, such as Loar (1988) and Block (1986), accept the thought experiments but propose another kind of content - narrow as opposed to wide - which captures the person's subjective point of view and serves the purposes of psychological explanation. Narrow contents capture what earthlings and their twin earth counterparts have in common, and explanations that ignore narrow contents miss crucial generalizations. If so, what is narrow content and how is it connected to wide content?

Loar and Block take narrow content to be 'conceptual role', which is defined in terms of a concept's inferential connections to other concepts. The main challenge for this view is to find a non-arbitrary way of constraining the relevant connections, so that each psychological state can turn out to possess a determinate narrow content, and to explain how this constrains its truth-condition (see Semantics, conceptual role). Another conception of narrow content, originated by White (1982) and championed by Fodor (1987), is that narrow content is a function from context to wide content. One challenge for this approach is to define the operative notion of context and to specify narrow contents informatively, rather than by abstraction from wide contents. Also, although the distinction between wide and narrow content acknowledges a systematic discrepancy between ordinary attitude attributions and scientific psychological explanation, and is motivated by a respect for both, one might wonder whether there really are two kinds of content or merely one kind described in two different ways.

It is difficult to assess the competing views because none of them has yet been developed in any great detail. A plausible if tentative assessment is that the distinction between wide and narrow content is well-motivated but not well-formulated. It is well-motivated since, in many cases, a thought's truth-condition is not wholly determined by what is in the head, and yet what is in the head does determine, independently of environmental factors, the thinker's perspective. Also, as Frege first recognized, wide content is too coarse to distinguish distinct perspectives on the same state of affairs or otherwise mark relevant differences in cognitive role. Realizing this, opponents of narrow content have suggested syntactic form or computational role as a surrogate for narrow content. However, this suggestion cuts things too finely: it fails to reckon with the possibility that mental representations of different forms or different computational roles might nevertheless embody the same cognitive perspective.

Content, indexical

Many of our thoughts are about particular individuals (persons, things, places, ...). For example, one can spot a certain Ferrari and think that it is red. What enables this thought to latch onto that particular object? It cannot be how the Ferrari looks, for this could not distinguish one Ferrari from another just like it. In general, how a thought represents something cannot determine which thing it represents. What a singular thought latches onto seems to depend also on features of the context in which the thought occurs. This suggests that its content is essentially indexical, contextually variable much as the content of an utterance such as 'I am hungry' depends on who utters it and when. The indexical model of singular thought is not limited to thoughts about individuals one perceives, but applies also to thoughts about individuals one remembers or has been informed of, such as an old bicycle or Christopher Columbus. In each case, a certain contextual relation, based on perception, memory or communication, connects thought to object.

Our thoughts do not merely represent what the world is like. Many of our thoughts manage to latch onto particular individuals (persons, things, places,…), and how this is accomplished needs to be explained. If, for example, one thinks of the bird on the window sill that it is a sparrow (the thought is expressible by 'That bird is a sparrow'), there must be something about the thought which makes it about *that* bird (see Demonstratives and indexicals). It might seem that the object of a thought must be uniquely determined by some component of the thought. This view is analogous to Frege's view that the 'sense' of a linguistic expression determines its reference (see Frege, G. §3; Sense and reference). The idea is that *how* something is represented determines which thing is represented. That is, the subject component of the thought, expressible in this example by the demonstrative description 'that bird', imposes a certain condition whose satisfaction by a certain individual makes it the object of the thought. This condition is the same no matter who entertains the thought, no matter where or when. The trouble with this view is that one might not represent the thing in question with enough specificity to single it out from all other birds. Indeed, one might even misrepresent it - perhaps what one takes to be a sparrow is actually a porcelain figure.

Here is an alternative view. An individual is singled out as the object of the thought not because it satisfies a condition represented in the thought but because the thought is causally connected to it. That is, as Tyler Burge (1977) has suggested, a thought latches onto something by way of bearing a certain contextual relation to that particular individual. If this is correct, then facts about the circumstances in which the thought occurs, and not just atemporal facts about its character, are relevant to the determination of its object. Two widely separated people with similar perceptual experiences (or the same person at different times) could have thoughts of exactly the same character, expressible by 'That bird is a sparrow', and yet be having these thoughts about different birds. One might be correct, the other mistaken. This suggests that singular thoughts are true or false only relative to a context. As John Perry (1993) describes them, they are 'essentially indexical'.

To explain how this can be, we need to distinguish the type of thought that both people have from the particular occurrence (or token) of that type which each has (see Type/token distinction). Tokens of the same thought type can be about distinct objects because singular thoughts are 'token-reflexive', much like indexical expressions. For example, the reference of the indexical 'I' depends on who utters it; of 'here' on where it is uttered; and of 'tomorrow' on when it is uttered. As a result, the sentence 'I will be here tomorrow' is neither true nor false in itself but only relative to a particular tokening of it. That is, a given utterance of it is true if the maker of that utterance will be at the place of the utterance on the day after the utterance. Different people, or the same person at a different place or time, would say different things with these words. Notice that there is also a sense in which everyone who utters 'I will be here tomorrow' says the same thing - utterances of the sentence are type-identical, but their truth-conditional contents differ in the way just described. Singular thoughts are similarly token-reflexive and indexical in content, because their objects are determined only relative to their context of occurrence. The object is not thought of as the unique object of a certain sort, that is, under a definite description (see descriptions), but in some contextually sensitive way. On this indexical view of singular thought, a thought represents a certain object in a context but without representing the context itself. The truth-condition of a particular token of the thought type, such as the one expressible as 'That bird is a sparrow', is not absolute but is contextually variable, in this case varying with the context of perception.

Not only can singular thoughts be about objects of perception, they can also be about individuals one remembers or has been informed of. François Recanati (1993) and Kent Bach (1987) both suggest that these cases involve uses of ‘mental indexicals’. One suggestive idea, developed most fully by Graeme Forbes (1989), is that, when we are introduced to (or otherwise learn of) an individual by name, we form a ‘mental file’ labelled with the name. We can later call up the individual by name. These mental files on persons and things are relatively permanent, but, as Recanati suggests, we seem to operate also with temporary files, labelled with mental counterparts of pronouns, on individuals currently singled out in perception or in conversation.

Content, non-conceptual

To say that a mental state has intentional content is to say that it represents features of the world. The intentional content of a belief can be characterized in terms of concepts: the content of the belief that fish swim is characterized by the concepts 'fish' and 'swimming'. The contents of beliefs are, for this reason, often described as conceptual. One way to explain this idea is to say that to have a belief, one has to possess the concepts which characterize the belief's content. However, some philosophers believe that certain mental states have non-conceptual contents: these states represent the world without the subject having to possess the concepts which characterize their contents. The main examples of these putative states are conscious perceptual experiences and the non-conscious states of cognitive information-processing systems (such as the visual system).

1 Conceptual and non-conceptual content

Beliefs and other propositional attitudes are individuated in terms of their contents. It is natural to think that having these propositional attitudes involves having concepts, construed here as items in the mind. If someone believes that *a is F*, then they must have the concept *F*, and the concept *a* - whatever concepts may be. This can be summed up by saying that beliefs have conceptual contents (see Propositional Attitudes). Some philosophers, for example Evans (1982) and Peacocke (1993), think that not all intentional mental states have conceptual contents. They hold that some intentional states have 'non-conceptual' contents: the contents of these states do not, in some sense, involve concepts.

How can a thinker's state have the content that *a is F* without the state 'involving' the concepts *a* and *F*? The best way to answer this question is to focus on the idea of 'possessing' concepts. In the case of states with conceptual contents - like beliefs - we can say that in order for a subject to be in these states, the subject has to possess certain concepts. Likewise, we can say that in order to be in a state with *non*-conceptual content, a subject does not have to possess certain concepts. But which concepts? It would be too strong to say that being in non-conceptual states does not require having any concepts at all - this issue should not be settled by the very definition of non-conceptual content. Rather, we should say that for a subject *S* to be in a non-conceptual state with content *P*, *S* does not have to possess the concepts which *S would* have to possess if *S were* in a conceptual state with content *P*.

If we call these concepts the concepts which are 'canonical' for *P*, then we can say that a state with non-conceptual content is one of which the following is true:

in order for a subject, *S*, to be in a state with a content *P*, *S* does not have to possess the concepts canonical for *P*.

The idea of concepts canonical for a certain content is just the idea that there are concepts which *essentially* characterize a given content (Cussins 1990: 382-3). The content expressed by the sentence 'snow is white', for example, is essentially characterized in terms of the concepts expressed by the words 'snow' and 'white'.

Why should anyone be interested in the category of non-conceptual content? Why should it be of any more philosophical interest than the category of non-red things? The reason is that intentionality seems closely bound up with having concepts. So it is a substantial thesis that there can be intentionality without possession of (the relevant) concepts (see Intentionality; Concepts). However, simply defining 'non-conceptual content' leaves open the question of whether there actually is any. So are there any states with non-conceptual content?

2 Varieties of non-conceptual content

The definition of non-conceptual content just given applies straightforwardly to some notions of content. States which carry 'information' (in Dretske's (1981) sense) have non-conceptual contents, since a state's carrying information is a matter of its co-varying in a nomic or reliable way with a certain phenomenon. For example: on this view we can say that a weather vane represents or indicates the direction of the wind. But it is obvious that the weather vane does not possess the concept of the direction of the wind.

However, it is debatable whether a state's carrying information is sufficient for the state to have representational content in any interesting sense. For one thing, since nomic co-variation is present wherever there is causation, this theory stretches the notion of representation to the point where it can apply to almost everything in the universe. Another problem is that informational states seem incapable of representing incorrectly; but the possibility of

incorrect representation seems essential to genuine representation. Something more must be added to turn mere informational states into states with genuine representational content (see Semantics, informational).

Two other kinds of state are claimed to have non-conceptual contents: states of the information-processing cognitive systems (for example the visual system) postulated by many psychological theories; and conscious perceptual experiences. Computational psychological theories claim that systems within the brain perform computations: that is, these cognitive systems compute functions by processing representations algorithmically. So the thinker (or the cognitive system) is in certain representational states, or states with content. These representational states are essentially specified in terms of certain concepts, but there is no need for the thinker to possess these concepts in order to be in these states. For example, Marr's (1982) theory of vision analyses visual information processing in terms of complex mathematical concepts; one need not master these concepts in order to process visual information. So these computational states, if they exist, are non-conceptual (see Mind, computational theories of; Vision).

The other kind of states which have been attributed non-conceptual contents are conscious perceptual experiences. The general idea here is that in perception many aspects of the world are presented to the perceiver; yet there is no need to suppose that the perceiver has a distinct concept for each aspect of the world which is so presented. Consider colour experience: is it plausible that each of us has a distinct concept for each precise shade of colour we are able to perceive? If it is not, this can be a reason for holding that perceptual experiences have non-conceptual contents: perception has a 'phenomenological richness' which is not constrained by the concepts the perceiver has (Evans 1982: 229-; other motivations for attributing non-conceptual contents to experiences are offered in Crane 1992 and Martin 1992).

Given that experiences have non-conceptual contents, how should this be explained? One of the most detailed accounts has been given by Peacocke (1993: ch. 3). At one level, the content of a perceptual experience is what he calls a 'scenario': a set of ways of filling out the space around a perceiver with properties and relations - for instance, with colour and shape properties. The experience's representational content is given by the scenario, because the experience is correct just in case the actual distribution of properties and relations around the perceiver belongs in the scenario. However, there is no requirement that the perceiver has all the concepts which essentially characterize the properties and relations in the scenario.

Opinions differ on whether the content of experience is wholly conceptual, wholly non-conceptual, or some mixture. Evans (1982) holds that it is wholly non-conceptual, while Peacocke (1993) holds that experiences can have many layers of content, some of which are conceptual and some non-conceptual (see Perception).

3 Problems with non-conceptual content

The notion of non-conceptual content could be criticized on two fronts. First, the application of the notion to a particular kind of mental state (perception, for example) could be criticized. Second, the very notion of non-conceptual content itself could be criticized.

John McDowell (1994: ch. 3) argues that to treat the content of experience as non-conceptual is to commit oneself to the idea which Wilfrid Sellars criticized as 'the myth of the given': the idea that experience involves being presented with an unconceptualized 'given' which the mind then goes on to conceptualize (Sellars 1956). McDowell argues that accepting this picture renders the relation between mind and world deeply problematic. By contrast, he argues that the content of experience is wholly conceptual. McDowell therefore accounts for the phenomenological richness of experience in a different way: he claims that where we have (for example) discrimination between colours, we may not have a distinct word for each colour, but we do have 'a recognitional capacity, possibly quite short-lived, that sets in with the experience' (1994: 57). And such a recognitional capacity is, he argues, fully conceptual.

Scepticism about the very idea of non-conceptual content can arise out of scepticism about the claim that there are concepts one must have if one is to be capable of having certain intentional states. Accepting this claim amounts to accepting a mentalistic version of a sharp distinction between analytic and synthetic statements - a distinction which has proved highly controversial (see Analyticity).

Contextualism, epistemological

The idea that norms vary with social setting has long been recognized, but it is only in the late twentieth century that philosophers have developed precise versions of epistemological contextualism, the theory that standards of knowledge and justification vary with context. Ordinary practice seems to support this rather than the 'invariantist' view that epistemological standards are uniform.

Suppose, for example, that having seen my children a minute ago, I assert 'I know my children are in the garden'. My neighbour Harold then says, 'Good, because an escaped prisoner is seeking hostages nearby'. I may then appropriately claim, 'On second thoughts, I do not know, I should check carefully'. Standards for knowledge appear to have shifted, since they now require further investigation.

Contextualism's greatest advantage is its response to scepticism. Sceptics raise radical possibilities, such as that we might be dreaming. The contextualist grants that such doubts are legitimate in the sceptical context, but holds they are illegitimate in everyday situations. Yet contextualism can appear to be an objectionable form of relativism, and may be accused of confusing standards that we apply in practical conversational contexts with the true standards that determine whether someone has knowledge.

1 Elements of the theory

Epistemological contextualism holds that standards of knowledge and justification vary with context. One form of the theory, call it 'subject-based contextualism', holds that epistemic standards depend on the knower's context. A more radical form, 'attributor-based contextualism', treats standards as varying with contexts of attribution. On this latter view, one attributor may legitimately claim that a person knows something while another may legitimately deny that the same person has the knowledge in question. Suppose Susan asserts, 'I know your children are in your garden; I saw them there a minute ago'. When my concern is to call the children to dinner, I attribute knowledge to Susan. But Harold, aware of an escaped prisoner seeking hostages nearby, would not attribute knowledge to her. What Susan knows depends on attributors' contexts, not only on her situation.

Contextualists also vary regarding contextual elements that determine standards. In the examples above, the relative importance of having correct information determines the strength of justification required. Other factors affecting epistemic standards might include: (1) doubts entertained; (2) doubts mentioned; (3) the topic under consideration; and (4) elements of the situation that affect the knower's reliability. David Lewis (1996) suggests that we follow a 'rule of accommodation', such that we tend to adjust our standards so as to count knowledge claims as true. Michael Williams (1991) argues for 'methodological necessities' which exempt propositions from doubt if considering them demands a shift in disciplinary focus. For instance, a molecular biologist may ignore concerns that shift the topic to particle physics.

Some contextualists believe that knowledge has a foundational structure (see Foundationalism). Foundationalists typically claim that knowledge is grounded in basic beliefs which have intrinsic epistemic credibility, and have that credibility as a result of belonging to some type of beliefs, such as beliefs about sensory experience. Contextualists deny both claims. Basic non-inferential beliefs have their status because they are permissible in context, and the belief type that is basic varies with context. We might expect that when discussing where to eat lunch, for example, basic beliefs include beliefs about ordinary material objects, whereas in conversation between physicists, basic beliefs include those about widely accepted theoretical views.

2 Advantages of contextualism

Beyond its compatibility with everyday practice, contextualism provides attractive responses to major philosophical problems. Here, let us consider the regress argument and scepticism. Suppose we hold that knowledge requires justification. The regress argument for foundationalism examines the nature of such justification. Either a belief has intrinsic credibility, and so is 'self-justifying', or it is justified by inference. If the latter, then the belief is ultimately inferred from (1) intrinsically credible beliefs, (2) unjustified beliefs, (3) an infinite regress of justification, or (4) a circular justification in which some beliefs appear in their own support. Foundationalists claim (1) is the only acceptable alternative, but they have had problems explaining and defending the notion of intrinsic credibility.

Those contextualists who allow a foundational structure propose an alternative resolution: justification ends in beliefs that are unjustified in their context. This is made plausible in two ways. First, the contextualist cites contextual factors that make it reasonable for agents to limit justification. For example, where all parties to an investigation agree on certain beliefs, there is no need to provide further justification. The contextualist may also appeal to Williams' concept of methodological necessity, according to which asking for justification can force inquirers to ignore disciplinary constraints. Second, contextualists claim that while justification ends with unjustified belief, demand for further justification can always be legitimated by special doubts about the unjustified belief.

The contextualist response to scepticism is even more attractive. Contextualists claim that sceptical doubts are legitimate, but only in the sceptical context (see Scepticism). Williams (1991) gives an illuminating response along these lines. He contends that scepticism presupposes 'epistemological realism', the view that there is only one correct order of appropriate epistemic inference. Sceptics believe that knowledge of 'the external world' must be justified on the basis of immediate experience. If so, we must argue from beliefs about sense impressions, or how things appear, to beliefs about the material world. Williams claims this order of inference is necessary only within the sceptical context. In other contexts, it is permissible to begin our justifications with beliefs about the material world; and in some situations, such as psychological investigations of perception, we may begin with beliefs about external objects and draw inferences about appearances. Epistemological realism is false, since context determines the proper order of inference.

Keith DeRose (1995) proposes, in contrast, a contextualist 'conditional theory' of knowledge. Suppose *S* has a true belief *p*. Where *S* would not believe *p* if *p* were false, the belief is 'sensitive'; where *S* would believe *p* even if *p* were false, the belief is 'insensitive'. DeRose endorses a 'rule of sensitivity': whenever someone asserts that *S* knows *p*, standards of knowledge are raised to require *S*'s belief *p* to be sensitive and the resulting standard applies for all beliefs in that context.

Suppose the belief *p* is that '*S*'s house is red'. If someone claims *S* knows *p*, the rule of sensitivity requires that if *S*'s house were another colour, *S* would not believe *p*. Philosophers typically evaluate subjunctive conditionals by considering whether, in possible worlds 'close' to the actual world but in which the antecedent of the subjunctive is true, the consequent is also true. 'If not *p*, *S* would still believe *p*', is true if, in worlds similar to our own but in which *S*'s house is not red, *S* can tell the colour of the house. Intuitively, at close worlds, *S* can determine the colour if *S* employs normal perceptual abilities. In contrast, let the belief *q* be 'I am a brain in a vat', where we have in mind the sceptical possibility that a brain is connected to a complex computer which simulates everyday experience. If someone claims *S* knows not-*q*, the rule of sensitivity demands that if *q* were true, *S* would not believe not-*q* (that is, *S* would believe *q*). This requires great epistemic ability, for we evaluate it by considering whether *S* believes *q* in worlds where *S* is a brain in a vat. The closest such world is far from the actual world, since in the actual world we cannot find out whether we are brains in vats. Once the rule of sensitivity raises standards so that we must consider such worlds, it does so for other beliefs in the context, including *p*. But in a world where *S* is a brain in vat, *S* will believe *p* even though *p* is false - in that world, *S* cannot determine the colour of anything! Thus, in contexts where *p* alone is considered, *S* knows *p*. But when *S* entertains *p* and a sceptical hypothesis, the rule of sensitivity raises standards to a level at which ordinary beliefs such as *p* are no longer known.

These responses to scepticism have the consequence, which Williams calls 'instability' and Lewis labels 'elusiveness', that when we raise sceptical doubts about ordinary knowledge, we change context and thereby 'destroy' that knowledge. In the sceptical context, the sceptic wins the debate. But this may be advantageous for contextualism, since it can explain both our judgment that we have knowledge in everyday situations and our feeling that sceptical doubts should be taken seriously.

3 Contextualism as relativism

In the case of contextualism, two objections underlie the charge of relativism. First, contextualism seems to accept statements of this form: '*S* knew *p*, but now, *S*'s evidence and reliability staying the same, *S* does not know *p*'. How can people know something at one time but not know it at a later time if they have the same justification they always had?

The second objection is more pressing. Straightforward relativists about truth - those who claim a proposition may be true for one group yet false for another group - appear to hold that a single proposition can be both true and false. This seems incoherent; the notion of truth is no longer in play but has been replaced by 'truth for' or 'truth from a point of view'. Subject-based contextualism escapes this worry, for while '*S* knows *p*' is true or false depending on *S*'s context, '*S* knows *p* in context *C*' is true from all points of view. The attributor-based contextualist, however, holds that truth of statements having the form '*S* knows *p*', or '*S* knows *p* in context *C*' (where '*C*' refers to the subject *S*'s context) are relative to attributors' context. It seems that there is no truth about whether *S* knows *p*, but only 'truth for' or 'truth from a point of view'.

To answer these objections we must treat 'knows' as an indexical term, analogous to 'I' or the demonstrative 'that' (see Demonstratives and indexicals). Following David Kaplan (1989), we may distinguish the 'character' of an indexical, the part of meaning that is constant, from the 'content', which changes. Roughly, the character of 'I' is a function from context to speaker, and the content of 'I' is the speaker on a given occasion of use. According to DeRose (1992), the character of '*S* knows *p*' requires that *S* should believe *p*, that *p* should be true, and that *S* should be in good enough epistemic position with respect to *p*. But what is 'good enough' varies with context, hence the content of a knowledge attribution is the level of epistemic position that counts as good enough in that context.

For example, the character of 'knows' in (*w*) 'Clara knows there is water in the glass' will require that Clara should believe there is water in the glass, that this belief should be true and that Clara should be in a good enough position to determine that there is water in the glass. But whether Clara is in a good enough position will vary with the attributor's context. Where the attributor's interest is in watering plants, the content of 'know' in (*w*) requires that Clara's position is good enough if she has the typical person's ability to identify water, in which case (*w*) is true. If, however, the attributor is engaged in important experiments, the content of 'know' in (*w*) requires that Clara's position is good enough only if she performed a chemical analysis, in which case (*w*) is false (assuming she has not done the analysis). There is no more mystery about the way truth conditions of (*w*) vary with context than there is about the way truth conditions of 'I lost my keys' and 'That is a rose' vary with context.

The second objection to relativism is easily handled, then: truth is relative to the attributor's context, but the notion of truth is preserved by treating knowledge claims as having an indexical component. What about the first objection? In any context, epistemic standards are set at one level, so we cannot employ two different sets of standards in evaluating a single sentence within that context. Therefore, we will reject statements of the form '*S* knew *p*, but, *S*'s evidence and reliability remaining the same, *S* no longer knows *p*'. Nevertheless, a corresponding 'metalinguistic' statement may be correct: '"*S* knows *p*" was true, but now, *S*'s evidence and reliability remaining the same, "*S* knows *p*" is false'. The contextualist argues that this is unobjectionable, given the indexicality of knowledge attributions.

4 Further objections

Let us consider four other objections:

(1) Knowledge may require greater uniformity than contextualism allows. Edward Craig (1993) has argued that the function of knowledge claims is to tag reliable information. But if epistemic standards regularly shift, we cannot rely on information gained in another context without continually re-evaluating our knowledge in each new situation. At the least, we need uniform standards of evaluation across broad areas of inquiry. The contextualist reply must grant that a core set of standards applies when special contextual factors are absent.
(2) In one context, Harold may say, 'Your children are in the garden', but once he learns about an escaped prisoner seeking hostages nearby, he would not make the same assertion. Assertibility conditions for the claim have changed, yet surely truth conditions have not. Does not the same thing hold for knowledge ascriptions? Assertibility conditions for knowledge claims vary with context, but why does this show that truth conditions for knowledge claims change also? The contextualist answer depends on arguing that speakers legitimately assert *p* only when they have adequate justification for claiming to know *p*. Thus, knowledge claims may not admit of a divide between assertibility conditions and truth conditions.
(3) Contextualism that allows unjustified beliefs is problematic. If there is no ground for non-inferential beliefs, surely we have not really provided justification. Foundationalists and coherentists will claim they can account for our permitting the absence of explicit justification. First, they would endorse the above view that contextualism

conflates assertibility conditions in a practical context with truth conditions that are not contextually determined. Foundationalists might argue that basic beliefs have minimal intrinsic credibility, but must be further justifiable given a legitimate challenge. Some coherentists claim that the most coherent theory provides grounds for accepting initial cognitive output from our sensory mechanisms. This output provides basic beliefs in a context, but is always justifiable in terms of broader theory. Contextualist response to such views requires detailed arguments about the plausibility of foundationalism and coherentism.

(4) Many sceptics believe they point to facts about the human condition that are so important they throw ordinary knowledge claims into doubt. As Barry Stroud (1996) argues, we have an 'objective conception of the world' which entails that almost all our beliefs about it can be mistaken. If this is a fundamental truth, then we cannot avoid scepticism merely by noting that in certain contexts we habitually ignore sceptical worries. The reply to this objection stresses first, that contextualism grants some truth to scepticism and, second, that unlike scepticism, contextualism emphasizes the practical origins of discourse about knowledge.

Contingency

People are often puzzled about the apparent contingency of the world. To say that something happens contingently is to say that it might not have happened, and to think of the world as contingent is to think that it might not have existed. Is it contingent? Those who ask this are asking whether there might not have been a world at all, or none that was at all like ours. Usually they are not asking whether there could have been a world which differed from ours only in its details: for example, one in which free agents made slightly different choices. That is an important question too, but a separate one. Some people reject the question of the contingency of the world as meaningless because they do not see how any answer to it could be verified. But such verificationism is controversial, and even if there is something wrong with the question it is still worth asking why people find it compelling.

On the classical medieval view, the existence of the world is contingent: it depends on God's choice. God's existence, however, is not contingent but necessary. It belongs to God's essence that he should exist. But there has long been the alternative idea, that the existence of the world is itself necessary. Many Neo-Platonists held (some still do) that the world exists because it is best that it should. If it is best that something should come about, then it must come about, and there is no room for God's choice in the matter. Other philosophers think that the world exists necessarily because it exists in virtue of scientific laws, which are themselves necessary. The idea that it is contingent, they suggest, is due to the confusion of scientific necessity with logical necessity. Logical necessity attaches only to statements - those that are instances of logical laws, often called analytic. The existence of the world itself is (scientifically) necessary; but the statement 'There exists a world like ours' is logically contingent - alternatives can be imagined without contradiction.

Spinoza also held that the world exists necessarily, but for neither of these reasons (see Spinoza, B. §4). For him it is necessary in its own right; existence belongs to the world's essence, as for the medievals it belongs to the essence of God. The necessity here is neither scientific nor logical, but metaphysical. Spinoza (1677) called the world 'God', but it lacks the personality of the orthodox God and is identified with Nature. He infers that because the world itself exists necessarily, there is no room for contingent events within it, but this is a mistake: one could hold, as Hegel did, that the nature of the world requires that there be certain contingencies within it.

It 'exists by the necessity of its nature alone': it is hard to see what this means, either for Spinoza or for his medieval predecessors who had said the same of God. It is not that it exists by definition - that we have formulated a concept of God or Nature in which existence is taken to be a defining characteristic. Spinoza was well aware (as were Anselm and Descartes) that our conceptions are likely to be defective and our definitions consequently irrelevant. It is that existence belongs to its essence as solubility in water belongs to the essence of sugar. So just as sugar is soluble necessarily, so God or Nature exists necessarily. Like Anselm and Descartes, Spinoza inferred that it exists. Aquinas and other medievals were more cautious, and held that this does not follow: what follows is that if there is a God its existence is necessary (see God, arguments for the existence of §§1, 2).

Spinoza also said that God is *causa sui*, here again following many predecessors, including Descartes (1641). This is often translated as 'cause of itself', but 'self-explanatory' might be better. Spinoza equated something's existing necessarily with its being self-explanatory, or requiring no explanation. Unfortunately this is a mistake. If to exist is part of something's essence we can still ask why it exists, just as we can ask why sugar is soluble. No doubt if it is sugar it is necessarily soluble, but we may derive that necessity from more general laws, and we may ask why there should be sugar at all. In general the fact that something is necessary does not remove the need to explain it. Complex mathematical truths can be explained in terms of simpler ones; perhaps elementary logical laws do not need explanation. But Descartes thought they did - they were fixed by God. Among those who hold that the basic laws of physics are necessary, some deny that they need explanation and others insist that they do. Some of these would feel that it strengthens, or at least fills out, their case to say that although these laws are scientifically necessary they are metaphysically contingent; in other words, that this world is itself metaphysically contingent - other worlds with alternative laws could have existed instead. But this is to repeat the mistake of equating what is necessary with what does not need explanation, and what is contingent with what does.

This mistake explains why people puzzle over the contingency of the world. What they really want to know is whether the world's existence requires explanation. It is a difficult question; but if we could solve it, any

explanation we provided would automatically tell us whether the world is contingent or not. Thus if the world is the free creation of God, it would not have existed if God had chosen differently, and it is metaphysically contingent. If, alternatively, as thought, it was created by a God who is bound to create the best of all possible worlds, there is no real possibility of God's choosing differently, and the world is metaphysically necessary (see Leibniz, G.W. §3). Leibniz (1697) refused to put the matter like this, and insisted on calling it contingent, just because it is created by God. There may be various reasons for this refusal, including a wish to continue to call God's choice 'free' even though God's own perfection left no alternative. But one of them is the thought that the world requires explanation, and that to call it necessary would be to imply otherwise.

We always seek explanations wherever possible. Leibniz (and many others) believed in a principle of sufficient reason, which says there is an adequate explanation for everything that exists or occurs. It is natural to hope that there is such an explanation; but then either there must be chains of explanations stretching back infinitely, or else there is some thing or event the nature of which removes the need for further explanation. Some have seen the Big Bang in this way, but it is evidently possible to speculate about why it occurred. There is no incoherence in the idea of something which had no cause and which did not depend on anything, but it would remain natural for us to seek an explanation for it even though there was none to be found. There is room for dispute as to what an explanation is, but if to explain the fact that Φ is to render it intelligible by reference to the fact that Ψ, it would seem that there might be some facts which were, in their own right, as intelligible as possible, like (perhaps) the fact that if *p* then *p*. The demand for further explanations could be terminated if we came to a fact of this kind. Some have thought the existence of God to be maximally intelligible, and the existence of the world not to be; but if 'intelligible' means 'intelligible to us', it seems plain that neither is maximally intelligible, and if that is not what it means, it is unclear what else it means.

A more defensible view would be that God's existence is 'self-explanatory' in that what makes his existence intelligible is his existence itself. It is arguable that we cannot explain anything except by tacitly presupposing the existence of God, because every explanation rests on certain principles of reasoning, and to suppose that these principles yield truth about the world is to suppose the sort of systematic match between the way we think and the way things are that could only be due to a purposive agent. If that were so, God's existence would be required to render anything intelligible, and if anything were proposed as an explanation of God, its explanatory power would derive from God's existence itself. This is as close as we could come, I think, to capturing the idea that God is *causa sui*. But it would not terminate the demand for explanations: we could still ask *why* God exists, and hope to find an answer which makes it more intelligible why there should be a God. And it does not entail the thesis that God's existence is necessary; nor does it follow from it.

Continuants

There is a common-sense distinction between terms such as 'statue' or 'chair' on the one hand, and 'concert' or 'war' on the other. A long-standing tradition in metaphysics has attached some significance to this distinction, holding that the first kind of term is used to name continuants, whereas the second kind is used to name events or processes. The difference is that continuants can be said to change, and therefore persist through change, whereas events do not. However, the distinction between continuants and events has been challenged on the grounds that no concrete object does, in fact, retain its identity through time. It has been suggested, for example, that unless we give up the notion of identity through time, we are faced with questions that we cannot answer. In addition, the notion that things persist through change is, apparently, threatened by a certain view of time. On this view there is in reality no past, present and future, but rather unchanging temporal relations between events. It has been suggested that such a view is committed to the idea that objects have temporal parts, and these by definition cannot persist through time.

1 Do objects persist?

Intuitively, you are the same individual as someone who existed yesterday, even though you have fewer brain-cells, your body temperature will have fluctuated and some of your desires may have changed. In contrast, a performance of a piece of music does not itself change: rather, it *consists* of a series of changes. An important part of the motivation for a distinction between continuants and events concerns our notion of responsibility. You can only be held responsible for the actions you performed yesterday if they really were your actions: you now and the person who performed those acts must be one and the same. This connection with responsibility might incline us to widen the class of continuants to include football clubs, religious orders and companies. Someone taking a company to court presumes that the company being taken to court today is the same as the one that violated the law last year.

For material objects, identity through time might plausibly be thought to be no more than spatio-temporal continuity. Put briefly, the continuity criterion states that an object, *a*, existing at one time *t* at place *s*, is identical with *b*, existing at a later time *t*′ at place *s*′, if and only if there is a continuous series of spatio-temporal points between *s* at *t* and *s*′ at *t*′ such that no point in that series is unoccupied by an object. This rules out the possibility of an object going out of existence for a period and then coming back into existence again. It also rules out discontinuous spatial motion. Two kinds of problem case arise for this account, however. Consider first a lump of bronze which is moulded into a statue of an old man by Rodin. This later falls into the hands of Henry Moore, who remoulds the statue to represent a pregnant woman. Finally, it comes into the possession of Elizabeth Frink, who turns it into an enormous head. What this obviously fictional example of aesthetic vandalism illustrates is that, although Frink's statue is spatio-temporally continuous with Rodin's statue, they are nevertheless not the same statue. Consider next an amoeba, A, which divides to form two amoebae, B and C. Both B and C are spatio-temporally continuous with A, but they cannot both be identical with A, for then (since 'identical with' is a transitive relation) they would be identical with each other. Clearly, spatio-temporal continuity is not the same relation as identity (see Identity §1).

In the face of this, we could look for a way of strengthening the spatio-temporal continuity criterion, or we could simply regard identity through time as a primitive relation, irreducible to any other. But both these options leave us with the apparently unanswerable question of whether it is B, or C, or neither, that is identical with amoeba A. A third, radical, approach is to reject altogether the notion of identity through time and with it the notion of a continuant. On this view, associated with Quine (1960), things, strictly speaking, do not persist through time. Rather, they are temporally extended in a sense closely analogous to the sense in which they are spatially extended (see Quine, W.V.O. §5). Just as a thing has different spatial parts at different places, so it has different *temporal* parts at different times. There is no question of a temporal part being identical to a later or earlier temporal part, any more than there is a question concerning whether your left foot is identical to your right foot. In the language of temporal parts, we can redescribe the cases above as follows: the collection of temporal parts that is Rodin's statue shares no temporal parts with either the Moore collection or with the Frink collection, though it does share a temporal part with the collection that is the lump of bronze. As for the amoeba, since no temporal part existing before the division can be identical with any part existing afterwards, there can be no question of B or C being the

same as A. What we have is simply a branching collection of temporal parts.

However, the notion of temporal parts is a controversial one. Effectively, it dissolves the distinction between objects and events in treating the former, more or less, as extended processes. So the temporal-parts view needs to explain why it is objects, not events, that are thought to change (see Events). In addition, the view must explain why we are apparently entitled to hold people responsible for past acts if the temporal part held responsible is not the temporal part that performed the act. Indeed, since temporal parts do not have duration, but exist only for an instant, how can the temporal parts of people be said to perform acts at all? The temporal-parts view can preserve the common-sense distinction between such things as chairs and concerts by pointing out that every temporal part of a chair is itself a chair, whereas it is *not* true that every temporal part of a concert is itself a concert. But is this enough to explain the facts about change and responsibility mentioned above?

2 Continuants and tenseless time

The appeal to temporal parts in dealing with the problem cases above is not simply a desperate manoeuvre: further motivation for the temporal-parts view comes from a certain view of time, namely one which denies the passage of time (see Change §2). Just what is involved in this denial should, however, be made more precise.

According to the *tensed theory of time*, tensed expressions such as ‘now’, ‘last year’, ‘in a few days’ time’, reveal a significant feature of time itself. For example, the presentness of a certain event is, on this view, a non-relational property of the time of that event; and also a transient property, in that the event will soon be past. The tensed theory is therefore associated with the view that time passes. According to the *tenseless theory of time*, in contrast, the presentness of an event is a relational feature of it: it is present only with respect to a particular time. Similarly, an event is only past with respect to a time, or group of times. On this view ‘present with respect to’ simply means ‘simultaneous with’, and ‘past with respect to’ simply means ‘earlier than’. So the only facts about presentness are trivial ones: a time is present with respect to (that is, simultaneous with) itself, past with respect to later times, and future with respect to earlier times. Times, therefore, do not on this view change in respect of their presentness. The tenseless theory is thus associated with the *denial* of time’s passage. We can present the contrast between the tensed and tenseless theories in terms of the account they give of what makes tensed assertions true:

Tensed theory

A particular utterance of ‘It is *now* very windy’ is true if and only if it is now very windy (or, equivalently, extreme windiness is present).
A particular utterance of ‘It *was* very windy’ is true if and only if it was very windy (or, equivalently, extreme windiness is past).

Tenseless theory

A particular utterance of ‘It is now very windy’, uttered at time *t*, is true if and only if it is very windy at *t*;
A particular utterance of ‘It was very windy’, uttered at time *t*, is true if and only if it is very windy at some time earlier than *t*;

where *t* is specified in tenseless terms (for example, ‘4 pm on 31 December 1999’).

It has often been assumed that the tenseless theory is committed to temporal parts, and the assumption is a natural one, for tenseless theory does away with what might have seemed a crucial disanalogy between time and space. As a place is ‘here’ to us just because we happen to be at that place, so, on tenseless theory, an event is ‘present’ to us just because we are at a point simultaneous with that event. Since objects have spatial parts, it is natural to assume that the tenseless theorist will suppose them to have temporal parts. There have, however, been attempts to reconcile the tenseless theory with the notion of continuants.

In temporal-part theory, the fact that *x* is *F* at time *t* is represented by the formulation ‘*x*-at-*t* is *F*’, where ‘*x*-at-*t*’ names a temporal part of *x*. There are, however, different ways of reporting the fact in question. For example, instead of qualifying the subject, *x*, with the term denoting a time, we could qualify the predicate: ‘*x* is *F*-at-*t*’. Alternatively, we could treat properties as *relations*, linking an object and a time: ‘*x* bears relation *F* to *t*’. Why are these ways of representing the facts thought to be alternatives to temporal parts? Because it is the whole, temporally extended, object which is *F*-at-*t* (on the first account) or which stands in certain relation to a time (on

the second account).

An objection to these supposed alternatives says that the intuition underlying the notion of continuants is that an object (in contrast to an event) is *wholly present* at each of the instants which compose its temporal extension. There can be no spatial analogue of this: an object is not thought to be wholly located at each of the points which constitute its spatial extension. The idea that something can be wholly present at different times avoids contradiction if we think of time as passing - that is the time at which an object is present as itself changing. Once we give up the idea that times can change in this way, and adopt the tenseless theory of time, we surely also give up the idea that an object can be wholly located at a time. Treating properties as relations between times and a temporally extended object merely disguises this fact (see Time §2).

Continuum hypothesis

The 'continuum hypothesis' (CH) asserts that there is no set intermediate in cardinality ('size') between the set of real numbers (the 'continuum') and the set of natural numbers. Since the continuum can be shown to have the same cardinality as the power set (that is, the set of subsets) of the natural numbers, CH is a special case of the 'generalized continuum hypothesis' (GCH), which says that for any infinite set, there is no set intermediate in cardinality between it and its power set.

Cantor first proposed CH believing it to be true, but, despite persistent efforts, failed to prove it. König proved that the cardinality of the continuum cannot be the sum of denumerably many smaller cardinals, and it has been shown that this is the only restriction the accepted axioms of set theory place on its cardinality. Gödel showed that CH was consistent with these axioms and Cohen that its negation was. Together these results prove the independence of CH from the accepted axioms.

Cantor proposed CH in the context of seeking to answer the question 'What is the identifying nature of continuity?'. These independence results show that, whatever else has been gained from the introduction of transfinite set theory - including greater insight into the import of CH - it has not provided a basis for finally answering this question. This remains the case even when the axioms are supplemented in various plausible ways.

1 The continuous, the discrete and the infinite

Greek mathematics was divided into arithmetic - the science of discrete magnitudes - and geometry - the science of continuous magnitudes. The basis for this division can be found in Aristotle's sophisticated discussions of space and time. The existence of incommensurable magnitudes, such as the side of a square and its diagonal (the ratio of which is $\sqrt{2}$), was already well known, as was the distinction between points and extended parts, however small, of a continuous whole. Aristotle argued that since two points can never be contiguous (either there is a separation between them or they coincide), a continuum can never be built up out of points. He defined a continuously extended whole as one which may be divided at any point into continuously extended wholes and concluded that it is necessary to draw a fundamental distinction between those wholes which are collections of parts and those which are 'given before their parts', that is, between discrete and continuous magnitudes.

So long as this division was in place (that is, until the seventeenth century) a question such as 'What is the (cardinal) number of points in a continuous line?' could not arise because it could not sensibly be asked. 'Continuity' was a primitive geometric concept. The situation changed, however, with the acceptance of Descartes' introduction of algebraic methods into the heart of geometry, allowing geometric curves to be defined by equations of 'motions' of points 'generating' them. This effectively swept aside the division between arithmetic and geometry, but without in any way confronting or resolving the problem of how to model the continuous by the discrete.

Newton and Leibniz explored and exploited the infinite divisibility of continua in their attempts to study continuous motions algebraically. Initially this exploration (infinitesimal calculus, analysis; see Analysis, philosophical issues in §1) moved freely between algebraic expression and geometric intuition, mediated by the concept of continuous motion. However, this led to the discovery of a number of 'pathological' functions, whose graphs cannot be pictured. For example, in a continuous plane, unlimited in extent, there is no limit to the number of wavelike, and hence continuous, oscillations that a point might execute within a given finite interval. So one might ask whether there might be a function which corresponds to a point oscillating with infinite frequency (that is, which is such that no matter how small an interval we take there will be an oscillation contained within it). Weierstrass' everywhere continuous but nowhere differentiable function seemed to 'describe' such a 'motion'. This kind of function contradicts the assumption, based on cases which can be pictured, that continuity and differentiability go together. So an account of continuity was required in terms not based on geometric intuition.

2 Numbering the continuum

Cantor's early attempts to characterize the structure of continua were natural extensions of the kind of work in analysis which led to discovery of these pathological functions. He established that the cardinality of the set $\mathbb{R}$ of real numbers is greater than that of the set $\mathbb{N}$ of natural numbers (see Cantor's theorem). He further proved that

there is a one-one correspondence between the points in a plane (the two-dimensional continuum) and the points in a line. So he already knew (writing $|A|$ for the cardinality of *A*) that

$$|\mathbb{R}\times\mathbb{R}| = |\mathbb{R}| > |\mathbb{N}|.$$

Cantor thus interpreted the problem of how to identify the nature of continuity as that of how to say when a given set of points in an *n*-dimensional space is to be considered a continuum. Having already defined the real numbers in terms of limits of convergent sequences of rational numbers, he made use of the more general notion of a 'limit point'. A point *p* is defined to be a limit point of a set *P* of points if in any neighbourhood of *p* there are infinitely many points of *P*. It can be proved that if *P* is infinite then it has at least one limit point. The set of limit points of *P* is denoted by $P^{(1)}$. The set $\mathbb{R}$ of real numbers (the 'continuum') is such that $\mathbb{R}^{(1)} = \mathbb{R}$. Sets with this property were called 'perfect'. But perfection does not serve to characterize continuity, as Cantor demonstrated with his 'ternary set', also called 'Cantor's discontinuum' (see Set Theory §5). This is the set of points of the closed interval (a 'closed' interval includes the points at either end) $[0, 1]$ which remain after infinitely many repetitions of the following procedure: divide each interval of the set into thirds, and in each case discard ('blank out') the middle third, leaving behind two closed intervals.

This set is dense in no interval of the continuum ($B \subseteq A$ is 'dense' in *A* if it is disjoint from no open interval of *A*), closed, perfect and contains no interior points: it is completely discontinuous.

Nevertheless, Cantor felt that perfect sets held the key since he was able to prove that no *denumerable* point set (that is, a set with the cardinality of the natural numbers) could be perfect. If a set *P* is finite, its first derived set $P^{(1)}$ is empty. For any *P*, either there is some finite *n* such that $P^{(n)}$ is finite and hence $P^{(n+1)}$ is empty, or there is not. For perfect sets there is no such finite *n*. So if this idea is to differentiate between continuous and discontinuous perfect sets it seems that *transfinite* indices of iteration need to be used. This was the context in which Cantor originally introduced transfinite ordinal numbers (see Set theory §2). He divided the ordinals into first and second number classes:

(1) $0, 1, 2, 3, \ldots$
(2) $\omega, \omega+1, \omega+2, \ldots \omega.2,\ \omega.2+1, \ldots \omega.3, \ldots \omega.\omega \ldots.$

(1) is the set of natural numbers, $\mathbb{N}$, which has cardinality $\aleph_0$ ('aleph-nought' or 'aleph-null'). Every ordinal α in (2) is such that the cardinality of $\{x\colon\ x < \alpha\}$ is $\aleph_0$. That is, these numbers represent all the possible orderings of a denumerably infinite set. Cantor proved ([1895, 1897] 1955: 169-73) that these two number classes cannot be put into one-one correspondence and that there can be no set with a cardinality in between the two. This justified calling the cardinality of (2) '$\aleph_1$'.

In this way the extension of the ordinal number sequence into the transfinite generates not only infinite ordinal numbers α but also infinite cardinal numbers $\aleph_\alpha$. It thus provides a scale of cardinal numbers on which one might hope to locate $2^{\aleph_0}$. The 'continuum hypothesis' (CH) expresses the claim that there is a one-one correspondence between the real numbers and the numbers in the second number class (in symbols, $2^{\aleph_0} = \aleph_1$), and another way of interpreting the claim made by the generalized continuum hypothesis (GCH) would be as saying that the two routes to generating higher infinite cardinalities (via power sets and via the number classes) coincide (in symbols, $2^{\aleph_\alpha} = \aleph_{\alpha+1}$ for every ordinal α). Although Cantor believed CH to be true (and Gödel (1939) proved it to be consistent with the axioms of set theory), he realized that there is no immediate guarantee that every cardinality will have a representative among the cardinalities of the number classes unless it can also be assumed that every set can be well-ordered, and hence has an ordinal number. If it were not the case that every set could be well-ordered, the cardinalities of those sets which cannot be so ordered would not be represented by cardinal numbers arising from the construction of the ordinal number sequence. Indeed it can be shown that in

Zermelo-Fraenkel set theory (ZF), GCH entails the axiom of choice and hence that every set can be well-ordered, whereas Cohen's independence result proves that the converse does not hold (see Cohen 1963-4).

3 Reactions to independence

Proof of the independence of CH (GCH) from ZFC (ZF plus the axiom of choice - see Set theory, different systems of §3) stimulated renewed interest in philosophical questions about the status of set theory and the epistemology of mathematics. Is there a universe of sets in virtue of which CH is either true or false, although at present we do not know which? If this is the case, how would we come to know more about it and hence hope to determine the truth-value of CH? The most radical reaction would undercut even these questions by interpreting the independence results as showing that the whole set-theoretic approach to problems of continuity was misguided: CH is undecidable because it does not make any real mathematical sense; it presupposes that we can sensibly talk about actually infinite sets, whereas we cannot. Less radical reactions assume that CH does make mathematical sense. The problem then is not merely how to determine whether or not it should be accepted, but to decide whether there is a basis for acceptance or rejection and, if so, what this might be. It might be argued that the situation of CH is analogous to that of the parallel postulate after it was proved to be independent of the remaining axioms of Euclidean geometry. The result in that case was a widening of the field of mathematical investigation to consider a whole variety of geometries in which the parallel axiom fails. Analogously, in set theory, explorations of systems in which CH holds and in which it fails have been carried out. Gödel (1947), however, contrasts the epistemological situations in geometry and set theory. In geometry the question of the truth or falsity of the parallel postulate retains its sense if the geometric axioms are interpreted as referring to the behaviour of rigid bodies, light rays and so on, but not otherwise - that is, the question of its truth or falsity has become an empirical question to be answered by reference to the contexts in which geometry is used; it is no longer a mathematical question. The question of the truth or falsity of CH, however, retains its sense only if the axioms of set theory are interpreted as referring to mathematical objects (sets), since these axioms have no direct empirical interpretation. Gödel himself believed that sets are mathematical objects which have an independent existence. He would thus interpret the proof of the independence of CH from ZFC as a demonstration that the axioms of ZFC do not contain a complete description of the set-theoretic universe. In this case there is a need to look for new axioms to complete the description. Several such axioms have been suggested and their consequences studied (see Set theory §1), but none has yielded anything approaching consensus on either their acceptability or that of CH.

Gödel's mathematical realism is not the only philosophical position which would underwrite attempts to resolve questions about the status of CH (and other proposed axioms of set theory) by studying the consequences for other areas of mathematics of accepting or denying it. It might be argued that what mathematical sense CH has is derived from its preformal connections with the problem of characterizing the continuous in terms of the discrete. If so, any determination should be based on its impact on the ever-widening area of mathematics connected with this problem. This approach relates philosophical issues about the status of set theory with other areas of mathematics, it does not resolve them.

Contractarianism

The idea that political relations originate in contract or agreement has been applied in several ways. In Plato's Republic Glaucon suggests that justice is but a pact among rational egoists. Thomas Hobbes developed this idea to analyse the nature of political power.Given the predominantly self-centred nature of humankind, government is necessary for society. Government's role is to stabilize social cooperation. By exercising enforcement powers, government provides each with the assurance that everyone else will abide by cooperative rules, thereby making it rational for all to cooperate. To fulfil this stabilizing role, Hobbes argued that it is rational for each individual to agree to authorize one person to exercise absolute political power. Neo-Hobbesians eschew absolutism and apply the theory of rational choice to argue that rules of justice, perhaps even all morality, can be construed in terms of a rational bargain among self-interested individuals.

John Locke, working from different premises than Hobbes, appealed to a social compact to argue for a constitutional government with limited powers. All men are born with a natural right to equal freedom, and a natural duty to God to preserve themselves and the rest of mankind. No government is just unless it could be commonly agreed to form a position of equal freedom, where agreement is subject to the moral constraints of natural law. Absolutism is unjust according to this criterion.

Rousseau developed egalitarian features of Locke's view to contend for a democratic constitution.The Social Contract embodies the General Will of society, not the unconstrained private wills of its members. The General Will wills the common good, the good of society and all of its members. Only by bringing our individual wills into accord with the General Will can we achieve civic and moral freedom.

In this century, John Rawls has recast natural rights theories of the social contract to argue for a liberal egalitarian conception of justice. From a position of equality, where each person abstracts from knowledge of their historical situations, it is rational for all to agree on principles of justice that guarantee equal basic freedoms and resources adequate for each person's independence.

T.M. Scanlon, meanwhile, has outlined a right-based contractualist account of morality. An act is right if it accords with principles that could not be reasonably rejected by persons who are motivated by a desire to justify their actions according to principles that no one else can reasonably reject.

1 The role of agreement

Contract accounts of justice are intuitively appealing. One explanation of their appeal is promissory obligation; if we agree to something we accept it, and when we agree on condition that others do, there is mutual reliance and grounds for holding all to their commitments. But the obligation of fidelity to promises does not adequately account for the intuitive force of agreement. Not all agreements involve promises. Also, it still must be explained why we should keep our promises, and a contractual promise cannot explain this duty. Hume (1748) explained promissory and contractual obligations by their public utility, and dismissed contractarian accounts of political relations as superficial.

But suppose we see the intuitive force of agreement as deriving not from promising, but from the liberal idea that rules of social cooperation should be based in individuals' consent and for their reciprocal benefit. Hume's argument cannot easily account for these ideas, for there is no clear connection between general utility and free consent; moreover, utilitarian principles do not guarantee institutions that benefit each individually. Here the idea of agreement calls upon deeper associations with democratic ideals of freedom and equality. Assuming that individuals are free and equal by nature or by right, it is natural to think that the political and social requirements they are subject to are contingent on their free agreement. Approached in this way, the ideas of contract and agreement can be applied to elucidate the requirements of freedom and equality.

Contract views differ depending on how the idea of agreement is specified. Who are the parties to the agreement? How are they situated (status quo, state of nature or strict equality)? What are their intentions, capacities and interests? What rights and powers do they have? What is the purpose of the agreement (political obligations, a constitution or social duties and institutions too)? Is the agreement actual or hypothetical, historical or non-historical? There is not one, but several contract views.

Two distinctions help to organize different views. First, *political contractarianism* concerns political and social relations associated with the idea of justice, including the legitimate role and powers of governments, basic rights and duties of citizens, property and its distribution, and the structure of economic relations. Issues of political justice underlie the work of the major representatives of social contract doctrine: Hobbes, Locke, Rousseau, Kant and Rawls. *Moral contractarianism* extends the idea of agreement to other moral relations. The most ambitious view would hold that all our duties and obligations, political and non-political, have their bases in agreement. None of the figures above profess this view.

Next, a *social contract view* maintains that certain basic duties and institutions are grounded in a unanimous agreement among all society's (competent) members. Unanimity illuminates the idea that justice, or morality generally, involves uniform public rules impartially applied to all individuals, which benefit each equally in some way. An *individual contract view* holds that certain basic duties or institutions originate in private or non-social agreement. Robert Nozick's libertarianism is an example (Nozick 1974); he depicts legitimate political power as originating not in social agreement, but in a series of discrete private contracts among isolated individuals (see Libertarianism).

Attention here is devoted to political and moral versions of the social contract tradition. There are two major traditions of social contract thought that deal with issues of political justice: *interest-based contract views* stem from Hobbes; *democratic contract views* derive from the natural rights theories of Locke, Rousseau and Kant.

2 Interest-based contracts and Hobbes

The common aim of interest-based views is to account for justice (or morality generally) in terms of what best promotes each person's enlightened interests. Norms of justice are depicted as the outcome of a mutually advantageous agreement. To carry this idea through, interest-based views contend that the basic desires and interests of individuals are fixed by their nature or circumstances, and are definable without any moral notions. Normally interests are explained as self-regarding or focused on oneself, although they need not be purely so (for example, Hobbes recognized 'conjugal affection' as widespread). What is important is that our final ends conflict. Agreement is then depicted as a rational compromise or bargain among essentially conflicting interests, where each party is willing to qualify the direct pursuit of their interests on condition that others do too. Essential to interest-based views is that all parties to the agreement must be made better off (or at least not worse off) than they would be without it.

Interest-based agreements are *historical* in that the parties have knowledge of their particular desires and circumstances. In Hobbesian interest-based views, historical circumstances are defined by a hypothetical, presocial and non-cooperative state of nature. The purpose of agreement from this baseline is to arrive at conditions of peaceable and efficient social cooperation, on the assumption that humans are mainly concerned with advancing their particular interests, are indifferent to the welfare of strangers and have no concern for morality and justice for their own sake. In interest views based on *convention*, the parties are similarly motivated, but their historical circumstances are defined by the current status quo. Because these views take the status quo as given, they do not so much seek to justify or critically assess prevailing cooperative norms as to explain them. Primary attention in this entry is devoted to Hobbesian views.

Hobbes' social contract has two roles (see Hobbes, T. §§6, 7). Its first purpose is as an analytical device designed to clarify the nature and necessities of political society. Its second purpose is normative: to justify absolute political power (see Absolutism §1). To discover the nature of political power, Hobbes imaginatively dissolves political society into its constituent parts, individuals, and then asks how it could come about from this initial situation. In the absence of effective political power individuals (or families) would inhabit a non-cooperative state of nature. Human nature is such that the primary ends of individuals are self-focused (or family-focused at best) and conflicting. Hobbes contends that the three motivations dearest to us are self-preservation, 'conjugal affection' and the means for commodious living. Given these and other motives, and uncertainty about the future, our desires are insatiable. But resources are scarce, so humankind is naturally competitive. Moreover, we are equal enough in strength of body and mind for the weakest to pose a threat to the strongest. Assuming these conditions, Hobbes' thesis is that a state of nature tends towards a state of war. In the absence of effective political power, it is irrational to be cooperative by keeping one's promises and commitments or trusting in the goodwill of others. To

protect one's person and possessions, each person's most rational strategy is one of 'anticipation', being prepared to attack others whenever circumstances seem favourable. The outcome is a collectively irrational situation where each person does what is best for themselves but all end up worse off than if they (jointly) had acted differently.

Hobbes' state of nature is the first recognition of 'prisoner's dilemma' situations central to modern game theory (see Decision and game theory §3). Hobbes resolves the state of nature dilemma with the social contract. What is needed to deliver those captured in a state of nature, or to avoid falling into one, is: (1) a system of norms which make social cooperation possible ('the laws of nature'); and (2) an effective sovereign to publicize and uniformly enforce positive laws that specify these 'articles of peace'. Hobbes' contract commissions one person to exercise political power sufficient to specify and enforce such laws. The contract is everyone's *mutual authorization* of a sovereign, not an agreement with him (a contract of government), for the sovereign cannot be contractually bound and remain sovereign (see Sovereignty). For Hobbes, to be adequate to its role, political power must be effectively absolute. The sovereign's role is to *stabilize* social cooperation by providing all with the assurance that cooperative norms are being enforced and that others will abide by them.

Locke argued that agreement to absolute political power is irrational. Constitutional regimes that limit power and secure individual rights provide better alternatives. Hobbes contests the stability of constitutionalism: effective sovereign power cannot be limited, divided or subject to the rule of law. History has decided matters differently. What endures in Hobbes is not his argument for absolutism, but the structure of his social contract (see Constitutionalism).

3 Contemporary Hobbesian views

This enduring legacy of Hobbes' social contract becomes apparent in the work of two contemporary Hobbesians, David Gauthier and James Buchanan. Both defend the classical liberalism of the *laissez-faire* economists. Gauthier does not try to justify executive political authority - it is unnecessary among fully rational beings. Instead he aims to (1) give a 'rational reconstruction' or morality, and (2) show how Western market society is grounded in reason (Gauthier 1986). Regarding (1), Gauthier contends that rationality is individual utility maximization. Morality, while it constrains the direct pursuit of utility, can be construed as an extension of principles of rational choice: rules which are rational to follow on condition that others do. Morality is then reduced to enlightened self-interest. It constitutes the restrictions on action that rational persons would mutually agree on to maximize individual utility.

Gauthier exhibits this neo-Hobbesian theme in (2), his defence of the 'system of natural liberty'. For Gauthier (and Buchanan) 'Economic Man' best characterizes human behaviour outside families: 'Economic Man is a radical contractarian in that *all* his free or non-coercive interpersonal relationships are contractual' (Gauthier 1986: 319). Contractual bargains typify market behaviour. Markets are 'an ideal of human interaction' because there we act free of moral constraints and perfect markets are efficient. But due to externalities markets often fail; each acts to maximize individual utility, and the outcome is non-efficient (see Market, Ethics of §1). It seeks to approximate the efficient equilibrium of perfect competition. But this requires cooperation, a joint strategy of mutual adherence to constraints on utility maximization. Gauthier's social contract supplies the cooperative norms needed to approximate perfect market interaction.

Hobbes contends that markets and property are not possible without political power; a sovereign must define property claims and enforce contracts. But Gauthier argues that rational agents in a state of nature would realize that the benefits of market relations outweigh the costs of predation and strife, so natural property and exchange would evolve among physical equals prior to any social contract. Market behaviour and private property are then presocial, part of our natural condition. Gauthier's social contract is not an agreement on political power, on the design of property or on markets as the mechanism for distribution. It is a bargain yielding a principle ('minimax relative concession') for correcting the externalities behind market failures and for distributing the fruits of cooperation (the 'cooperative surplus') arising outside private propertied market relations. This principle mimics the perfect market in that it distributes the benefits and burdens of cooperation according to each person's marginal contribution. Gauthier's social contract has a limited function, but a necessary one he believes, if peaceable and efficient social cooperation are to be possible.

Hobbesian views depict justice and morality as mutually advantageous norms that are rational to observe so long

as others do too. Providing everyone with assurance that cooperative terms will be uniformly complied with is essential for stability. However, even assuming that each benefits from the compliance of others, moral constraints often seem to conflict with our rational interests, and for many this is sufficient reason to disregard them. How can such 'free-riders' be persuaded that it is irrational to disregard moral constraints when circumstances appear favourable? To argue that virtue and justice are their own reward makes no sense on Hobbesians' instrumental view of morals. This problem explains why Hobbes gave the sovereign absolute power: no other way insures against free-riding, which undermines everyone's belief in the rationality of compliance. Gauthier's solution is non-political: free-riders acquire a reputation for unreliability and others refuse to cooperate with them; rationality therefore requires developing a disposition always to comply. This may convince people who continually interact, but what about strangers? The larger a society, the less effective reputation is as a deterrent, so under modern conditions it appears inadequate for stability. (For this reason Buchanan (1975) advocates a 'protective state' as one end of the social contract, to stabilize pre-political market relations.)

Hobbesian views collapse questions of justification into questions of (rational) motivation: to justify norms is to show they promote each person's existing interests. But many who currently benefit from the status quo would be greatly disadvantaged if Gauthier's or Buchanan's *laissez-faire* schemes were enacted (for example, monopolists, oligopolists, beneficiaries of government regulation and subsidies, and recipients of public assistance). What reason do they have for accepting contract arguments for reform? Can it seriously be argued that in mixed Western economies everyone would benefit by reverting to *laissez-faire*? History tells us this shift promises only further adverse consequences for those already naturally and socially disadvantaged, and even greater benefits for most who are already better off. Without resolving this motivational problem, the justificatory task of modern Hobbesian theories cannot be carried through on its own terms.

4 Conventionalism

Hume (§5) attacks Locke's contractarian account of political legitimacy and obligation. But he argues that rules of property and economic exchange, of promising, and of allegiance to governments might be explained as 'a kind of contract' (Hume 1748). A *convention* is a mutually beneficial social rule which people publicly accept and comply with because they believe others will too, and where the rule's benefits can be gained only if there is general compliance. The idea is often used for analytic or explanatory purposes, to clarify institutions or practices commonly accepted as part of the status quo. Conventional explanations of law and morality have been attempted (Harman 1977). The term 'social contract' is often applied, particularly by social scientists, to practices that exhibit the features of Humean conventions. Conventions are, like social contracts, mutually beneficial, but only in the weak sense that each person who participates is better off than they would be in the absence of any such rules. For example, virtually any property scheme can be explained as a convention, or 'social contract' in this weak sense. To call conventional accounts 'contractarian' is acceptable if it is recognized that, standing alone, they are explanatory and not normative. Each person's benefiting from a practice does not justify it, although it may explain why people continue to comply.

5 Democratic contract views and Locke

Freedom and equality are primary democratic ideals. The role of a social contract in Locke (§10), Rousseau, Kant and Rawls is to elucidate the requirements of these ideals in matters of political justice. If free persons all could, or would, agree to something from a suitable position of equality, the standards they would endorse embody requirements of democratic justice applicable to us so far as we aim to cooperate on terms of equal freedom and mutual respect.

Unanimous agreement among free persons equally situated serves different purposes for these thinkers. For Locke the social contract is a test of the legitimacy of existing constitutions; for Rousseau and Kant, it is also a standard for just legislation; and for Rawls it provides criteria for designing the basic institutions of society. Each defines the conditions of equality and the freedom of the parties to the agreement differently. But the general idea shared in common is that the justice of political institutions depends on whether they could, or would, be agreed to from a position of equal political jurisdiction (see Justice §5).

Democratic contract views maintain that, whatever the differences among individuals *de facto*, all persons are free and equal *de jure*, when each has the requisite capacities of reason, intellect and self-control to decide on their

good and comply with social requirements. Democratic contract views are therefore right-based, since they define agreement as subject to antecedent principles of right and justice, which are depicted as not reducible to non-moral interests (or any prior agreement based therein). Among these principles of right may be certain moral rights and duties which cannot be infringed upon or bargained away (as in Locke, Rousseau and Kant). Alternatively, principles of right may be implicit in an ideal of the person as free, equal and endowed with certain moral powers (as in Rawls), that is purportedly implicit in the public culture of a democratic society.

The democratic contract tradition originates with Locke's argument against royal absolutism. Locke contends that all are born with a natural right of equal freedom, by virtue of which no one may legitimately exercise political jurisdiction over another without their consent. Moreover, all have a natural duty to God to preserve themselves and the rest of humankind. Given these rights and duties (the 'fundamental law of nature'), Locke asks, how could legitimate political authority come about from a state of equal right as defined by a non-political but socialized state of nature? Locke contends that no constitution is just unless it could have been contracted into from this initial situation by a series of agreements wherein no one agrees to anything that makes them worse off than in a state of nature, and no one agrees to anything that causes them to violate the rights of others or their own duties. Royal absolutism could not be contracted into compatibly with these conditions, so it is unjust. A constitutional monarchy with a limited franchise could be contracted into, as could other constitutional schemes; each is then, according to Locke's criterion, a legitimate constitution (see Liberalism §5; Legitimacy §2).

Locke's social contract, like those of Hobbes, Rousseau, Kant and Rawls, is hypothetical. Locke's claim is not (as Hume thought) that a constitution is legitimate only if it actually originated in agreement in the past among our forebears: one '*cannot* by any *Compact* whatsoever, bind *his Children* or Posterity' (Locke 1690: §116; original emphasis). Rather, it is legitimate only if it could have originated in agreement from a state of equal political right. Actual agreement is irrelevant for purposes of applying this criterion.

Locke's social contract is also historical, for it envisages agreement from a (hypothetical) state of nature where everyone has full knowledge of their situation and interests there. Unlike Hobbes' state of nature, this situation is moralized - a 'natural community' - for each therein recognizes natural rights and duties as constraints upon everyone's pursuit of their interests, and upon what can legitimately be agreed to.

It is objected that hypothetical contracts have no binding force (see, for example, Dworkin 1977). This assumes that hypothetical agreements provide an account of the political obligations of individuals. But this is not the primary purpose of Locke's social contract (or Rawls', Kant's or Rousseau's either). The main purpose of Locke's agreement is not to explain the duties of individuals, but the justice of political institutions. Promising plays no role in explaining the effectiveness of Locke's criterion when construed as a test of political legitimacy. Locke does give an individual contract account of political obligation. Persons are obligated as citizens and subjects to bear allegiance to a legitimate government in perpetuity, not by birth, but only once they actually give their express consent to join a regime. Those who withhold such express consent to join still consent tacitly to obey the laws upon benefiting from them. Express and tacit consent are actual, not hypothetical; moreover they are individual commitments, not social agreements requiring participation by all society's members. Locke's account of political obligation is subject to many objections (see Consent; Obligation, political §3), but it is not essential to his social contract view.

6 Rousseau's democratic contract view

In Rousseau (§3) and Kant the social contract provides a point of view from which to decide on just legislation and articulates the ideas of moral freedom (autonomy) and the common good (Rousseau 1762; Kant 1797).

All social contract views assume that everyone benefits by social cooperation. Rousseau makes a stronger claim: certain essential human capacities and interests can only be realized in society, and only then where society has been structured democratically. While natural freedom typifies a state of nature, there we are not (in contrast to Hobbes) rationally prudent, but 'stupid, short-sighted animals', moved by instinct and appetite tempered by natural compassion. Our capacities for reason (prudential and moral) are socially interdependent. But human reason, moral sensibilities and deeper human affections have always been distorted by gross inequalities in power and property. Consequently, humankind has been prevented from realizing these great goods and moral and civic freedom. How is it possible to achieve a society where people realize these benefits, without arousing the will to domination,

subservience and other vices of history? Rousseau addresses this problem with his *contrat social*.

The general will expresses the idea that moral and civic freedom are attainable only when institutions satisfy principles free and equal citizens can give to themselves. One's particular will is the interests constituting one's individual good. Hobbes' social contract underscores the inevitable conflict among particular wills, and arbitrates by requiring all to compromise for mutual benefit. Rousseau calls this 'sum of particular wills', the 'will of all'. The general will, by contrast, is what we would jointly will if we subordinated our particular wills and adopted the perspective of free and equal citizens, each motivated by the good of the public and all its members (see General will).

The general will is initially expressed through the social contract. Its object is the common good. For Rousseau (Kant and Rawls too) divergences among individual wills does not mean there cannot be a supreme end all might share which regulates individuals' free pursuit of their particular ends. Such a common good is possible, and is necessary if all are to realize moral and civic freedom. The common good is, first, the institutions and laws that protect the fundamental ('natural') rights of individuals and define a just constitution. Among these are democratic institutions which provide for the civic freedom of citizens and their equal (and for Rousseau direct) participation in legislative deliberation and decision. Beyond this, the common good is whatever laws are willed in legitimate democratic procedures that advance the interests of each member of society in their freedom and security.

For Rousseau (and Kant), the social contract and the general will also express the elusive idea of moral autonomy (see Autonomy, ethical). Natural liberty, or acting as one pleases on the basis of inclination, is a kind of slavery, 'while obedience to a law we prescribe to ourselves is liberty' (Rousseau 1762: I, 8). We have a fundamental interest in realizing such freedom, since then (according to Kant) we fully realize the powers of practical reason constituting our humanity. Moral freedom, or autonomy, is attainable only in society, and (for Rousseau) only then where regulative institutions conform to principles free and equal citizens could give to themselves reciprocally. To act autonomously is to act compatibly with the general will for its own sake: to willingly subordinate the free pursuit of one's particular good to the common good, as articulated by the social contract.

7 Rawls' democratic contract

Rawls (§1) transforms and develops the contract views of Kant, Rousseau and Locke. The object of agreement is principles of justice that apply not just to laws and the constitution, but to other basic social institutions that regulate the distribution of wealth and opportunities to occupy favourable social positions. Rawls aims to provide 'the most appropriate moral basis for a democratic society' (1971: viii).

Consider a problem in Locke's social contract: since the parties have historical knowledge of their differences in a state of nature, it is not irrational for some to agree to alienate their rights of equal political jurisdiction to gain the benefits of political society. Nor is it wrong; for Locke political rights, unlike liberty of conscience and basic freedoms of the person, are not inalienable. If so, it is not unjust to restrict voting rights constitutionally to propertied males, making the rest 'passive citizens'. However democratic Locke's starting position, he does not require a democratic constitution with equal political rights.

Rawls' contract is designed to prevent arbitrary contingencies (for example, prevailing property distributions) from affecting the justice of political and social institutions. A contract is non-historical the more those party to it abstract from knowledge of circumstances (actual or hypothetical) that would advantage or disadvantage people who occupy certain positions. (The idea is already implicit in Rousseau and Kant, for neither envisage social agreement as transpiring in a state of nature.) Rawls' original position is wholly non-historical since contractors are placed behind a complete 'veil of ignorance' regarding their particular situations, so none can take advantage of their social circumstances, their natural talents, their particular conceptions of the good or prevailing historical conditions. By situating his parties symmetrically, Rawls makes them strictly equals, and carries to the limit the ideal of equality behind democratic contractualism.

Rawls argues that the conception of justice that would be agreed to in the original position is neither utilitarian nor perfectionist, but a Kantian account: justice as fairness. Its main principles afford equal rights to certain basic liberties and opportunities and regulate distributions of wealth and access to social positions so that they benefit everyone, with primary attention given to those least advantaged. These principles for institutions, along with individual duties of justice, mutual aid and mutual respect, comprise the general will of free and equal moral

persons. Just laws and institutions constitute their common good. In complying with and acting for the sake of these principles and institutions, citizens are morally autonomous, for they act on and from a law they give to themselves, out of their rational and moral powers.

Hegel (1821) argued that contract doctrines are individualistic and incompatible with community. This criticism may apply to Hobbesian accounts of our relations with strangers but, as for Rousseau and Kant, arguably Hegel misunderstood the role of the general will. Contemporary communitarians (for example, Sandel 1982) restate Hegel's criticism, contending that Rawls' original position presupposes abstract individualism (see Community and communitarianism). Rawls (1993) contends this interpretation is mistaken.

8 Right-based versus interest-based views

Hobbesians and others object that right-based views (especially non-historical ones) are not genuinely contractual, since they involve little or no bargaining. Given their moral assumptions and shared interests in a common good, agreement is superfluous; the same standards can be derived by impartial decision by one individual. Now, one can simply stipulate that contracts and agreements involve bargains among essentially conflicting interests. This has the peculiar consequence that most major proponents of social contract theory (Locke, Kant, Rousseau, Rawls) are not contractarians at all. (Even Hobbes' contract is not a negotiated bargain but a mutual authorization of an effective sovereign.) But not all agreements involve bargains or negotiated compromises among conflicting interests. People with diverse ends often commit themselves to norms on condition that others do, to achieve a shared end of great importance (for example, in religious associations or marital vows). The point of agreement is not to resolve conflict (there may be none), but to tie down the future to keep the parties from deviating from the shared purposes and norms of association. Democratic views involve agreement in this sense of a *shared precommitment* among citizens to relations that maintain their freedom and equal status. This agreement is not effective because of mutual promises. Rather, it establishes principles and institutions which bind citizens perpetually into political relations as equals, and so prevent them from later changing their minds or surrendering to temptations that undermine the good of others or everyone's shared interest in justice.

Being rational bargains, interest-based contracts involve mutual advantage: each person gains, given their historical starting position (status quo or state of nature). Being shared precommitments, right-based agreements involve reciprocity: everyone benefits as measured from a fair baseline of equality. Interest-based agreements between serfs and landlords to increase productivity on condition that serfs get 10 per cent of the surplus are mutually advantageous but not reciprocal, for the terms are unfair and the starting position is unjust. In the reciprocal agreements of democratic views, there is no guarantee that each person will benefit compared to the status quo. The purpose of reciprocal agreements is not to improve on the status quo by preserving its injustices, but to provide a criterion for assessing current injustice and the measures required for reform.

But if there is no guarantee that one will benefit, how can everyone be expected to accept the terms of reciprocal agreements? Many favoured by an unjust status quo will not; if their sense of justice is weak or vacillating, it may be irrational for them to. For democratic theorists this does not count against the validity or reasonableness of right-based contracts. It is a motivation problem belonging to the process of transition from an unjust to a just society. Unlike Hobbesians, for democratic views justice is not defined as a compromise among given and essentially conflicting interests. So justifying a moral conception does not involve showing each person, whatever their desires, that justice benefits them. Rather, a conception is justified when it conforms to reasonable persons' considered judgments of justice and reasonableness.

To Hobbesians this appears circular and unenlightening. They construe moral justifications reductively, as questions of rational motivation given non-moral interests. Hobbesians encounter a different problem; namely persuading those now advantaged by the status quo that it is rational to accept norms that would be agreed to by self-interested members of a hypothetical state of nature. Some sort of motivation problem is then confronted by any contract view that does not take the current status quo as the basis for agreement. And in the history of social contract thought, there are no significant normative doctrines of status quo agreement.

9 Moral contractualism

The idea that not only justice, but morality generally, is based in general agreement has not been worked out in

detail. Rawls and Gauthier suggest it, but their arguments are limited to justice. The primary difficulty with this thesis is that many duties do not seem to involve reciprocity or mutual advantage. The duties of parents to their young children are not contingent upon children observing their duties to honour and obey their parents. And duties forbidding cruelty to animals or the destruction of nature and valuable species are not easily explained in contractual terms.

One significant effort to account contractually for, not all, but many moral duties is T.M. Scanlon's right-based view. Scanlon (1982, 1988) is influenced by the idea of universal acceptability implicit in Kant's claims that as moral beings we should regard ourselves as legislative members of a kingdom of ends. Scanlon depicts morality as the result of 'hypothetical co-deliberation'. It is 'a theory according to which an act is right if it would be required or allowed by principles which no one, suitably motivated, could reasonably reject as a basis for informed, unforced general agreement' (1988: 15). Interpreting this, imagine a community of free and informed agents, each of whom is conscientious, sincere and motivated by a desire to justify their actions, ends and expectations to everyone else similarly motivated. Morality is the set of public norms which such idealized persons would jointly affirm and commit to, aware that these norms are to regulate their activities and serve as the final standards for justification, criticism and settling conflict.

Reasonableness is a central idea in Scanlon, Rawls and right-based views. It is conceived of as a fundamental moral category, not reducible to rationality. One can be fully rational, by acting best to promote one's interests, and still be unreasonable. A reasonable person respects the needs and interests of others and is not prone to overreaching. To be reasonable is to be responsive to the individual reasons of others. It involves a willingness to limit one's expectations and constrain one's actions and ends by rules that respect the legitimate pursuits of others. Reasonableness also includes a willingness to justify one's actions by reasons others could publicly endorse in uncoerced general agreement. Reasonableness is not altruism. One can be unreasonably altruistic, by promoting a majority's interests while undermining the needs of the few. Reasonable persons are equitably fair-minded; they regulate their acts in ways that respect everyone's basic interests.

Scanlon's contractualism yields an account of morality's subject matter, and so of moral objectivity and validity. Many moral theories assume there is a perspective from which to achieve unanimity, at least among rational persons similarly informed. For example, in Locke's intuitionist moral epistemology, the fundamental law of nature is self-evident to the right reason of every informed and unbiased rational being. Contractualism reverses the order of dependence between unanimity of judgment and moral principles. Rather than moral judgments being true when they match a prior moral order, the moral order is specified in terms of ideal judgment and agreement. Moral truth is then defined by referring to the principles to which free persons would agree under ideal conditions. There is no order of moral facts antecedent to hypothetical co-deliberation and agreement. Moral truth is then discoverable by us, not by rational intuition or moral sense, but by deliberating on what free, informed moral agents equally situated would reasonably agree to.
